Identification of transcriptional regulators for the *Ustilago maydis mig* genes

Dissertation

zur Erlangung des Doktorgrades

der Naturwissenschaften

(Dr. rer. nat.)

dem

Fachbereich Biologie

der Philipps-Universität Marburg

vorgelegt von

Yan Zheng

aus Changchun, China

Marburg / Lahn, November 2007

The work in my thesis was carried out from May 2004 until August 2007 at the Max-Planck-Institute for Terrestrial Microbiology, Marburg, Germany, under supervision of Dr. Christoph Basse.

By the Biology department of the Philipps University, Marburg as doctoral thesis
accepted on:

Date of oral examination: 18. 12. 2007

First reviewer: Prof. Dr. Regine Kahmann

Second reviewer: Prof. Dr. Hans-Ulrich Mösch

The following paper was in preparation by the date of submission of the present thesis:

Yan Zheng, Jan Kief, Kathrin Auffarth, Jan Farfsing, and Christoph W. Basse. 2007. The *Ustilago maydis* Cys₂His₂-type zinc finger transcription factor Mzr1 regulates fungal gene expression during the biotrophic growth stage.

Pledge

I certify that my thesis entitled “Identification of transcriptional regulators for the *Ustilago maydis mig* genes” was carried out without any unlawful devices. I did not use any other than the described literatures or technical devices.

This thesis has never been submitted before to any other university and has not been used before any examination.

Marburg, 05.11. 2007

Yan Zheng

Summary

The basidiomycete fungus *Ustilago maydis* is a plant pathogen. It can infect maize plants specifically and depends on the plant host for pathogenic development. This fungus has become an interesting research model for plant-fungus interactions.

A maize induced gene family, the *mig* genes, has been identified in *U. maydis*. This gene family contains *mig1*, the *mig2-1* to *mig2-5* gene cluster, and *mig2-6*. All *mig* genes showed strongly plant induced expression patterns and were predicted to be involved in the plant-fungus interactions. Detailed analysis of the *mig2-5* promoter has uncovered a consensus motif (5'-CCAC/AC/A-3'), which is present in multiple copies in all *mig2* promoters and whose activity specifically depends on the sequence triplet 5'-CCA-3' (5'-TGG-3'). On this basis, I considered C2H2 zinc finger and Myb proteins in *U. maydis* as potential regulators for *mig* genes. Candidate genes were analyzed by a PCR-based deletion approach.

I could show that deletion of *mzr1*, which encodes a C2H2 zinc finger protein, strongly decreases the expression level of *mig2-5* after plant inoculation. In addition, another C2H2 zinc finger protein called Biz1 has been found to be involved in the transcriptional activation of *mig* genes (M. Vranes and J. Kämper, unpublished). Conditional overexpression of both *mzr1* and *biz1* is sufficient to induce transcription of several *mig* genes under culture conditions. Furthermore, I could show that the truncated Mzr1 protein expressed in *E. coli* could specifically bind to the *mig2-5* promoter *in vitro*. Apart from this, another C2H2 zinc finger protein, named Znf23, was found to be involved in *mig* gene regulations. I could show that the expression of *mig* genes in the *znf23* deletion strain was stronger than in the wild type strain after plant infection.

These results suggest that Mzr1 is a direct positive regulator to *mig2-5*, while Znf23 appears to negatively influence *mig* gene expression. The implications of these results are discussed.

Zusammenfassung

Ustilago maydis ist ein pflanzenpathogener Basidiomycet. Er infiziert spezifisch Maispflanzen und ist in der Vollendung seines Lebenszyklus auf diesen Wirt angewiesen. Der Organismus wurde zu einem interessanten Forschungsmodell für Interaktionen zwischen Pflanze und Pilz.

Mit den *mig*-Genen wurde in *U. maydis* eine Genfamilie entdeckt, deren Expression in Anwesenheit der Pflanze induziert wird. Diese Familie enthält das Gen *mig1*, das Gencluster *mig2-1* bis *mig2-5* und das Gen *mig2-6*. Alle *mig*-Gene zeigen ein stark pflanzeninduziertes Expressionsmuster. Daraus wurde gefolgert, dass sie eine Rolle in der Interaktion zwischen Pilz und Pflanze spielen. Eine detaillierte Analyse des *mig2-5* Promotors führte zur Entdeckung des Konsensusmotivs (5'-CCAC/AC/A-3'), das in allen *mig2*-Promotoren in mehreren Kopien vorkommt und dessen Aktivität von der Anwesenheit des Sequenztripletts 5'-CCA-3' (5'-TGG-3') abhängig ist. Diese Tatsachen führten zu der Hypothese, dass C2H2-Zinkfingerproteine und Myb-Proteine mögliche Regulatoren der *mig*-Gene sind. In dieser Arbeit wurden Kandidatengene über PCR-basierte Gendeletion analysiert.

Dabei konnte gezeigt werden, dass die Deletion von *mzr1*, einem Gen, das für ein Zinkfingerprotein codiert, zu einer drastischen Reduktion des Expressionslevels von *mig2-5* nach der Pflanzeninfektion führt. Unabhängig wurde mit *Biz1* ein weiteres Zinkfingerprotein identifiziert, welches ebenfalls an der transkriptionellen Aktivierung der *mig* Gene beteiligt ist (M. Vranes und J. Kämper, nicht veröffentlicht). Die konditionale Überexpression von *mzr1* und *biz1* ist hinreichend, um unter Kulturbedingungen die Transkription mehrerer *mig* Gene zu induzieren. Es konnte ausserdem gezeigt werden, dass ein in *E. coli* exprimiertes verkürztes Mzr1-Protein *in vitro* spezifisch an den *mig2-5* Promotor bindet. Weiterhin wurde ein drittes C2H2 Zinkfingerprotein namens Znf23 identifiziert,

das an der Regulation der *mig* Gene beteiligt ist. In Abwesenheit von *znf23* fällt die Expression der *mig* Gene nach der Pflanzeninfektion deutlich stärker aus als in der wildtyp-Situation.

Aus diesen Ergebnissen lässt sich folgern, dass Mzr1 ein positiver Regulator von *mig2-5* ist, während Znf23 die Expression der *mig* Gene negativ beeinflusst. Die Schlussfolgerungen aus diesen Ergebnissen werden diskutiert.

List of abbreviations

Amp	ampicillin
BSA	Bovine serumalbumine
bp	base pair
Cbx	Carboxin
CM	complete medium

1 Introduction

1.1 Plant-fungus interactions

It is estimated that there are about 1.5 million species of fungi in nature (Grayer *et al.*, 2001). Like all other organisms that cannot obtain nutrition by photosynthesis, fungi depend on plants for their carbon and energy source. The majority of fungi lives on dead plant tissue and recycles the nutrients for plant reuse. Thus, fungi play a key role during the nutrient cycle in nature.

After a long time of evolution, nutrient sources of some fungi have been changed from dead plant tissue to living plants. In fact, most of the fungi, which interact with living plants are advantageous to host plants. Furthermore, among them some fungal species evolved that acquired the ability to break the balance with the host and thus became pathogens. Interestingly, in most plant populations, there are individuals that can resist fungal infection.

In 1898, W. Farrer discovered that resistance to rust in wheat is inherited (Farrer, 1898). Then R. H. Biffen's discovery in 1905 about resistance to yellow rust in wheat caused a breakthrough in breeding for disease resistance (Biffen, 1905). But only a decade later, research about resistance in wheat to wheat stem rust showed that host resistance had been overcome by variants of the pathogen (Stakman, 1917; Stakman *et al.*, 1918). The battle between resistant plant cultivars and their pathogens has been described as the 'boom and bust' cycle (Crute, 1985). H. H. Flor's studies demonstrated that flax is resistant to a particular physiologic race of *Melampsora lini* only when the cultivar carries a dominant resistance gene corresponding to a dominant avirulence gene of the pathogen (Flor, 1942, 1946, 1971; reviewed in De Wit, 1992). This is the basis for gene-for-gene relationships of plant-fungus interactions (Barrett, 1985; Crute, 1985; Day, 1974; Islam *et al.*, 1991; Keen, 1982; Michelmore *et al.*, 1988; Parlevliet, 1983; Thomas, 1991). During the past few years, many models, mainly involving bacterial pathogens,

have been postulated to explain this gene-for-gene relationships. The tobacco (*Nicotiana tabacum*) *N* gene was isolated from *N. glutinosa* and confers resistance to most strain of tobacco mosaic virus (Whitham *et al.*, 1994). *Xa21* confers resistance to over 30 distinct strains of the bacterium *Xanthomonas oryzae* pv. *Oryzae*, which causes leaf blight in rice (Song *et al.*, 1995). The tomato *Pto* gene, which was the first race-specific disease resistance gene to be isolated, confers resistance to races of *Pseudomonas syringae* pv. *tomato* that carry the *avrPto* gene (Martin *et al.*, 1993). Because of the larger genomes and the fact that transformation protocols do not exist for many phytopathogenic fungal species, in particular for most obligate biotrophs, avirulence genes have only been cloned from a few fungal species (Knogge, 1996). The first disease resistance gene to be isolated was *Hm1* from maize, which confers resistance to the leaf spot fungus *Cochliobolus carbonum* (Hammond-Kosack *et al.*, 1997; Johal *et al.*, 1992; Walton, 1984).

1.2 *Ustilago maydis*

Maize smut is distributed throughout the world (Davis, 1936). Common smut of maize has been of interest to biologists for more than 250 years. Some reports that discuss maize smut with some precision appeared in 1760 (Anon *et al.*, 1891; Christensen *et al.*, 1963). The cause of common smut, the basidiomycete fungus *Ustilago maydis* (which was carried to Europe by the early Spanish explorers), was described first by O. Brefeld in 1883 (Brefeld, 1883). He proved that the young meristematic tissues above ground were subject to infection. Brefeld also recognized that *U. maydis* undergoes multiple morphological transitions during pathogenic growth. The complete life cycle of the fungus was still unknown until 1927 when the sexual stage was discovered. The initiation of pathogenic development is characterized by the morphological switch from yeast-like budding cells to tip-growing hyphae (Christensen *et al.*, 1963; reviewed in Kahmann *et al.*, 2000). Haploid *U. maydis* cells arrest in the G2 phase after

recognition of compatible mating partners (Garcia-Muse *et al.*, 2003; Snetselaar *et al.*, 1996) and form a conjugation tube. This directed tip growth towards the pheromone source (Snetselaar *et al.*, 1993, 1996) leads to cell fusion and the formation of dikaryotic hyphae. Dikaryotization occurs after hyphal fusion of opposite mating types (Christensen *et al.*, 1963; Hanna *et al.*, 1929). After mating, the filamentous dikaryon depends on the maize host for further pathogenic development. Dikaryotic hyphae grow in the meristematic region of the plant and cause galls in early stages of proliferation of tissue (reviewed in Paredes-Lopez *et al.*, 1995). During this stage, the fast growing, branching hyphae invade plant tissue by intra- and intercellular growth (Snetselaar *et al.*, 1994). Massive fungal proliferation causes the tumour formation. Finally nuclear fusion and fragmentation of hyphae lead to the formation of the diploid teliospore (Ehrlich *et al.*, 1958; reviewed in Basse and Steinberg, 2004). Before germination, these cells reside in the soil until the spore wall cracks. Meiosis takes place and promycelium is formed, which contains the meiotic products that are able to restart the sexual life cycle (Christensen, 1963; Kahmann *et al.*, 2000).

It has been confirmed that haploid sporidia of *U. maydis* contain the mating-type loci *a* and *b* (reviewed in Kahmann *et al.*, 2000; Kronstad *et al.*, 1997). The *a* locus consists of two alleles called *a1* and *a2*. It encodes a pheromone/receptor system that enables mating in response to pheromone recognition by the receptor of the opposite mating type (Bölker *et al.*, 1992). The *b* locus encodes a pair of homeodomain proteins *bE* and *bW* that in nonallelic combinations dimerize to an active transcription factor required for filamentous growth and pathogenic development (Kronstad *et al.*, 1990; Romeis *et al.*, 2000; Gillissen *et al.*, 1992; Kämper *et al.*, 1995; Brachmann *et al.*, 2001).

U. maydis has become an interesting molecular model to investigate the plant-fungus interaction based on its tight dependency on the plant host. The complete genome of strain UM521 has been sequenced and released by the Broad Fungal Genome Initiative (<http://www.broad.mit.edu>), which made it possible to investigate gene functions in more detail. An efficient PCR-based system for gene

replacement has been developed (Kämper, 2004), which makes it easier to investigate the function of specific gene(s) by single or multiple gene deletions.

1.3 *mig* genes in *Ustilago maydis*

U. maydis depends on the host plant to complete its pathogenic development. Presumably, a lot of *U. maydis* genes and specific plant compounds are involved in the plant-fungus interaction process. Identification of such stage specific genes in *U. maydis* may offer insight into the mechanisms for plant-fungus interaction. Many stage specifically expressed genes have been identified in *U. maydis* (Basse *et al.*, 2006; Bohlmann 1996; Brachmann *et al.*, 2001, 2003; Romeis *et al.*, 2000; Schauwecker *et al.*, 1995; Urban *et al.*, 1996; Wösten *et al.*, 1996). A maize induced *mig* gene family has been detected (Basse *et al.*, 2000, 2002). This gene family consists of *mig1*, the highly homologous *mig2-1* to *mig2-5* cluster genes and *mig2-6*. The five *mig2* genes, *mig2-1* to *mig2-5*, are arranged as direct repeats within a 7.1 kb DNA region and reside on chromosome XXII of *U. maydis* strain 521 (**Fig.1**). The *mig2-6* resides on chromosome XXI. The C-terminal 81 amino acids of Mig2-6 are 58% identical to its closest homologue, Mig2-4 (Farfsing *et al.*, 2005).

Figure 1. The *mig* locus.

A. *mig1* locus (cited from Basse *et al.*, 2000). **B.** *mig2* locus (cited from Basse *et al.*, 2002).

Figure 2. Amino acid alignment of *mig2* genes.

Amino acid alignment of the six *mig2* genes (cited from Christoph Basse). Conserved Cys residues are marked in red.

All *mig* genes encode small, secreted, cysteine-containing proteins (**Fig.2**) and lack homology in the NCBI database. They show very similar expression profiles during fungal growth: as assessed from Northern blot analysis and microscopy of reporter strains carrying *eGFP* under various *mig* promoters, all genes exhibit strongly upregulated transcription levels after plant penetration and maintain a high expression level until the formation of teliospores, whereas expression is absent or only faintly detectable during axenic growth (**Fig.3**). Transcripts of

mig2-1, *mig2-4* and *mig2-5* were detectable 2 days after plant infection and peaked 2 days later, whereas transcripts of *mig2-2* and *mig2-3* were undetectable until 4 days after plant inoculation and then declined. Among them, *mig2-5* showed highest expression levels, followed by *mig2-4*, *mig2-2*, *mig2-1*, and *mig2-3* (Basse *et al.*, 2002). Neither starvation conditions, which have been reported to mimic fungal gene expression *in planta* (Coleman *et al.*, 1997; Pieterse *et al.*, 1994; Van den Ackerveken *et al.*, 1994), nor growth in the presence of tumor extracts could induce *mig1* or *mig2-1* expression under culture conditions (Farfsing *et al.*, 2005). After deletion of *mig1* or the entire *mig2* cluster, no significant influence could be detected on pathogenic development. Based on their extracellular localization and plant-specific expression profile, Mig proteins were predicted to be involved in plant-fungal interaction (Basse *et al.*, 2000, 2002).

Figure 3. Expression profile of *mig* genes.

A. Expression profile of *mig1* (cited from Basse *et al.*, 2000), the constitutive expression of the *cbx* gene reflects the amount of *U. maydis* RNA loaded. **B.** Expression profile of *mig2* (cited from Basse *et al.*, 2002), the constitutive expression of the *ppi* gene reflects the amount of *U. maydis* RNA loaded.

Jan Farfsing had analysed the transcriptional start position and promoter sequences of *mig2* genes. His results showed that the sequence context of all determined transcriptional start sites was CCACA^T/A_C. A putative TATA-like element (TLE) was found in the promoters of all *mig2* genes. Furthermore, the TLE appeared to be specifically required for *mig2-5* promoter activity *in planta*, which suggested that inducible *mig2-5* promoter activity relies on cooperation with a putative TATA box-binding protein. To investigate the *mig2-5* promoter in more detail, the JF1 strain was constructed, in which the 870 bp intergenic region between *mig2-4* and *mig2-5* was fused to the *eGFP* (enhanced green fluorescent protein) gene at the transcriptional start ATG and the construct was ectopically integrated in single copy into the *ip* locus of the solopathogenic *U. maydis* strain SG200 (*a1mfa2bE1bW2*). The GFP signal was strongly expressed in strain JF1 after plant penetration. By promoter deletion analysis, it was shown that elements required for inducible expression were located between position –234 and –161 relative to the start ATG, while adjacent regions on either side contributed to promoter activity. Based on the JF1 strain, a series of promoter mutation experiments were performed. In these experiments the GFP fluorescence was no longer detectable *in planta* when six 5'-CCA-3' motifs within positions –215 to –169 in the *mig2-5* promoter were substituted by the sequence 5'-GTC-3' (*U. maydis* strain JS12). This suggested the strong requirement for several 5'-CCA-3' containing motifs in this short stretch of the *mig2-5* promoter to confer inducible promoter activity (Farfsing *et al.*, 2005).

1.4 Myb and C2H2 zinc finger regulators

There are a number of different families of zinc finger proteins that contain multiple cysteine and/or histidine residues and use zinc coordination to stabilize their folds (Berg *et al.*, 1996,1997; Coleman, 1992; Klug *et al.*, 1995; Wolfe *et al.*, 1999). Cys₂His₂ zinc finger proteins were the founding members of the zinc finger

superfamily and were first noted as repeating domains in the TFIIIA sequence (Brown *et al.*, 1985; Engelke *et al.*, 1980; Hanas *et al.*, 1983; Miller *et al.*, 1985). The DNA-binding activity of these domains has been the major focus of investigation (Choo *et al.*, 1997). A number of studies were done to determine the principles of zinc finger-DNA recognition (Desjarlais *et al.*, 1992; Kim *et al.*, 1995; Nardelli *et al.*, 1991, 1992; Thukral *et al.*, 1992). It has been clear that these fingers possess the consensus sequence (F/Y)-X-C-X₂₋₅-C-X₃-(F/Y)-X₅- Ψ -X₂-H-X₃₋₅-H, where X represents any amino acid and Ψ is a hydrophobic residue (Wolfe *et al.*, 1999).

Sp1 (named according to the original purification scheme that included Sephacryl and phosphocellulose columns) was one of the first transcription factors to be purified and cloned from mammalian cells (Dyanan *et al.*, 1983; Kadonaga *et al.*, 1987). It was shown to recognize and specifically bind to GC-rich sites within the simian virus 40 promoter via three Cys₂His₂ zinc-finger motifs. A similar DNA-binding domain has been found in many developmental regulators, including the *Drosophila* embryonic pattern regulator Krüppel (Kadonaga *et al.*, 1987). Subsequently, some transcription factors were identified that had zinc-finger motifs highly similar to those of Sp1, thereby defining a novel class of Sp1-like proteins or Krüppel-like factors (KLF, Turner *et al.*, 1999; Black *et al.*, 2001; Dang *et al.*, 2000; Suske, 1999). Like Sp1, factors of the Sp1-like/KLF family can bind various GC-rich DNA elements and regulate transcription. All these C2H2 zinc finger proteins share the same structure: a short peptide loop with a small β -hairpin, followed by an α -helix held in place by a zinc ion. In the folded state, the α -helix contacts directly the major groove of the DNA (Choo *et al.*, 1997).

The Myb protein family is a group of functionally diverse proteins found in plants and animals. Members of this family share a similar domain organization. The most conserved region is the DNA-binding domain located in the N terminus, which is composed of three imperfect repeats of 51-52 amino acids that recognize

the canonical Myb-binding site C/TAACNG (Biedenkapp *et al.*, 1988; Howe *et al.*, 1991). After binding, Myb proteins function to facilitate transcriptional activation (Goff *et al.*, 1992).

In my work, zinc finger and Myb proteins in *U. maydis* were selected as candidates for the identification of possible *mig* regulators.

1.5 Aim of work

The aim of my work was the identification of possible *mig* regulators to get insight into the regulatory network, by which *U. maydis* is able to recognize and to invade into maize plants. In my work, the *mig2-5* promoter was used as major target for the *mig* regulator identification. It was planned to show the influence of regulator(s) to the *mig2-5* promoter both in culture and *in planta*. To confirm the function of the identified regulators, it was planned to verify the direct interaction between the promoter(s) and the *mig2-5* promoter both *in vitro* and *in vivo*. On another hand, I want to show the influence of the identified *mig2-5* regulator(s) to the other *mig* genes. Based on these experiments, I want to characterize the role of *mig* regulator(s) during pathogenic development of *U. maydis*.

2 Results

2.1 Myb and zinc finger proteins in *Ustilago maydis*

Based on the results of the *mig2-5* promoter mutation experiments, a promoter region has been uncovered in more detail (Farfsing *et al.*, 2005). Inspection of the sequence context of the *mig2* genes led to the consensus sequence 5'-CCA-3'. This underlined the importance of CCA-containing motifs for inducible *mig2-5* promoter activity.

The zinc finger and Myb proteins are usual DNA-binding proteins found in eukaryotes. Many zinc finger proteins that have been identified can bind to various GC-rich DNA elements and regulate transcription. On this basis, Myb and Znf (zinc finger) proteins in *U. maydis* (**Table 1**) were selected as candidates for possible *mig2* regulators.

Table 1. Myb and Zinc-finger proteins in *U. maydis*

Proteins	MUMB um number	MUMDB Homology	Myb/Znf domain

The um number represents the original gene name obtained from MUMDB (<http://mips.gsf.de/genre/proj/ustilago>). Myb and Znf represent Myb and Zinc-finger proteins.

2.1.1 Expression analysis of zinc finger and *myb* genes in *Ustilago maydis*

Based on the expression profiles of *mig* genes, I presumed that the putative positive *mig* regulators should possess the same expression patterns. To examine expression patterns of *myb* and zinc finger genes in *U. maydis* during different pathogenic development stages, reverse transcription PCR (RT-PCR) quantification was done. RNA was isolated from three different stages: the haploid stage of strain FB1, the dikaryotic stage of strains FB1xFB2 grown on solid CM charcoal medium, and the stage *in planta* five days after inoculation. After reverse transcription, the cDNA samples were used as templates for quantification by PCR. Gene specific primers for the six *myb* and 20 *znf* genes, together with the primers for the *mig2-5* and *ip* (*cbx*) genes (controls), were used to quantify the transcription profiles for these genes during the three different development stages. The *ip* gene is constitutively expressed in all developmental stages (Broomfield *et al.*, 1992), whereas the *mig2-5* gene is strongly upregulated *in planta*.

First, the PCR cycle number was tested and 34 cycles were found to be suitable to allow detection and quantification of all probes. Primers used for each gene are described in **Table 2**.

Table 2. Primers used for RT-PCR quantification

Gene	Primers*	Gene	Primers*	Gene	Primers*
<i>myb5</i>	JF219/JF220	<i>znf11</i>	JF280/JF281	<i>znf25</i>	JF282/JF283
<i>myb6</i>	JF221/JF222	<i>znf12</i>	JF241/JF242	<i>znf27</i>	JF261/JF262
<i>myb7</i>	JF223/JF224	<i>znf13</i>	JF243/JF244	<i>znf29</i>	JF263/JF264
<i>myb8</i>	JF225/JF226	<i>znf14</i>	JF245/JF246	<i>znf31</i>	JF265/JF266
<i>myb9</i>	JF227/JF228	<i>znf15</i>	JF247/JF248	<i>znf36</i>	JF267/JF268
<i>myb10</i>	JF229/JF230	<i>znf16</i>	JF249/JF250	<i>znf40</i>	JF269/JF270
<i>znf5</i>	JF231/JF232	<i>znf18</i>	JF251/JF252	<i>mig2-5</i>	m25gsa/m25gsb
<i>znf6</i>	JF233/JF234	<i>znf21</i>	JF253/JF254	<i>ip</i>	CBS1/CBS2
<i>znf8</i>	JF235/JF236	<i>znf22</i>	JF255/JF256		
<i>znf9</i>	JF237/JF238	<i>znf23</i>	JF257/JF258		

The length of these primers is 20 bp (average); the length of the PCR products for each gene is approximately 800 bp. *See Table 8 for sequence and details.

Quantification of the PCR products upon gel electrophoresis showed that the *znf21*, *znf22*, *znf23* and *znf25* exhibited similar expression profiles to *mig2-5* during the three stages tested (**Fig.4**): they were strongly upregulated during the five day-tumor stage, whereas expression was absent or only faintly detectable during axenic growth (FB1 and FB1xFB2). This result made these genes prime candidates for corresponding regulators *in planta*.

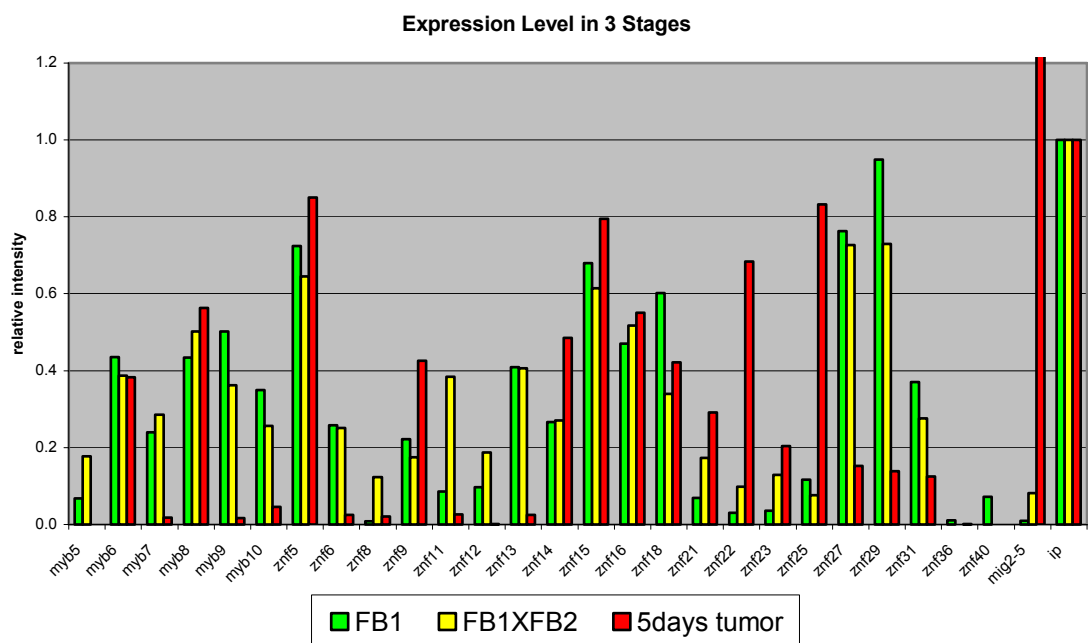

Figure 4. RT-PCR quantification of *myb* and zinc finger genes (abbreviated with *znf*) in *U. maydis* during different stages.

Signal intensities were obtained from RT-PCR analysis. RNA was isolated from three development stages: FB1, FB1xFB2, and infected plant tissue five days after inoculation. After reverse transcription, the cDNA templates were used for PCR (34 cycles). The green columns represent gene expression levels in the haploid stage, the yellow columns represent gene expression levels during the dikaryotic stage in culture, and the red columns represent gene expression levels in plant tumors five days after inoculation.

2.2 Deletion analysis of the candidate genes

Approximately 17.4 Mb of the estimated 20.5 Mb genome of *U. maydis* strain UM521 have been sequenced by Bayer CropScience AG (Monheim, Germany). Recently, the Broad Fungal Genome Initiative has established a more complete sequence of UM521 (19.7 Mb, <http://www.broad.mit.edu>). The availability of the genomic sequence made it possible to analyze the function of specific gene(s) by generating defined deletion mutants.

To investigate the function of the prime candidates that were chosen from the results of the RT-PCR analysis, I constructed deletion strains of these genes. The gene deletion procedure in my work involved the generation of two homologous flanking regions of the target gene, ligation of the flanking regions to a resistance cassette, reamplification of the entire construct by PCR, and the standard transformation in *U. maydis*. For *U. maydis*, flanking sequences of about 1 kb in length had been determined to be ideal for target gene replacement constructs (Kämper, 2004).

The bacterial hygromycin phosphotransferase gene (*hph*), which confers resistance to hygromycin, is widely used as a dominant selection marker in *U. maydis* (Wang *et al.*, 1988). A hygromycin resistance cassette with a shortened *hsp70* promoter and a terminator sequence from the *Agrobacterium nos* gene was constructed to minimize the commonly used *hph* resistance cassette from 3061 to 1871 bp; it was flanked by distinct *Sfi*I restriction sites on either site in plasmid pBS_{hhn}, which was used for ligation with the two flanking regions after *Sfi*I digestion. The central five nucleotides of the *Sfi*I recognition sequence are variable, and thus allowed directed cloning of the three fragments.

The two flanking regions were amplified from genomic DNA of the wild type strain 521 by PCR using primers that introduced the respective *Sfi*I sites to the left (CACGGCCTGAG↓TGGCC) and right (GTGGGCCATCT↓AGGCC) flanking regions. After digestion with *Sfi*I, the left and right flanking fragments were ligated to the *hph*-cassette (see above). Based on the two non-compatible *Sfi*I sites,

self-ligations were successfully prevented. Hence the ligation reaction gave three different products: (1) the *hph*-cassette ligated with the left flanking fragment; (2) the *hph*-cassette ligated with the right flanking fragment; (3) the *hph*-cassette ligated with both left and right flanking fragments. Subsequently, the ligation products with both flanking fragments were isolated upon agarose gel electrophoresis. The purified ligation product was cloned into the pCR4-TOPO plasmid vector and cloned in *E. coli*. After sequencing, the confirmed plasmid was used as template for a second PCR amplification using the outer primers. The amplified DNA fragment (left flank-*hph*-right flank) was transformed into the *U. maydis* strain JF1. Homologous integration was verified by PCR using outer primers of the gene ORF (see **Table 8**) and the *hph*-cassette specific primers *hhn5* and *hhn3* (**Fig.5**). In addition, gene specific primers (see **Table 2**) were used in a diagnostic PCR test to determine the absence of the target genes in the *U. maydis* genome. The absence of a PCR product could verify the deletion of the target gene.

Deletion mutants of *znf3*, *znf4*, *znf5*, *znf7*, *znf14*, *znf20*, *znf21*, *znf22*, *znf23*, *znf25*, *myb2*, and *myb8* were generated based on strain JF1. Among these genes, *znf21*, *znf22*, *znf23* and *znf25* exhibited similar expression profiles to *mig2-5* during the three stages tested (**Fig.4**); *znf3*, *znf4*, *znf5*, *znf7*, *znf14*, *znf20*, *myb2*, and *myb8* also showed stronger expression levels *in planta* than in culture. However, the construction of *myb1*, *myb3*, *znf9*, and *znf12* deletion mutants was not successful. 48 individual transformants were generated for each deletion mutant and none of them showed correct PCR results. This could be explained by the fact that these genes are crucial for *U. maydis*.

Figure 5. PCR based gene deletion procedure.

Gene deletions were generated as follows. The 5' region (left fragment) of the gene to be deleted was amplified with PCR using the primer pair P1/P2, and the 3' region (right fragment) was amplified with the primer pair P3/P4. The PCR products were ligated to the *hph* resistance cassette (*hph*-cassette) after *SfiI* digestion. The ligation product is used as template for a second PCR using primers P1 and P4. The PCR product was used for transformation of *U. maydis*. Homologous integration was verified with PCR using primer pairs P0/hhn5 and P5/hhn3. hhn5 and hhn3 are *hph*-cassette specific primers, and P0 and P5 bind within the genomic context outside of the left and right fragments (outer primers). PCR products are obtained only if a homologous integration has taken place.

2.2.1 Plant infection with deletion mutant strains

Next, I examined whether strains deleted in candidate genes for potential *mig2-5* regulators were affected in *mig2-5* gene expression during plant infection. For this purpose, maize plants were inoculated with the individual strains and infected plant tissue was harvested three days after inoculation. The GFP fluorescence signals in these mutant strains were examined by fluorescence microscopy. Only

the *znf22* deletion mutant showed a significantly reduced GFP expression level: it emitted very weak GFP fluorescence after plant infection (**Fig.6**) and furthermore many hyphae without fluorescence were observed. This illustrated that the Znf22 protein is required for the *mig2-5* promoter activation *in planta*. For the remaining mutant strains, no significant influence on GFP expression levels could be detected after plant infections.

Figure 6. Comparison of GFP fluorescence in strains JF1 and JF1 Δ *znf22*.

Infected maize tissue samples were assayed by differential interference contrast light (DIC) and epifluorescence (GFP) microscopy. Hyphae are marked by red arrows. Exposure time for fluorescence photography is indicated in the upper right corner of the pictures.

A. Maize tissue three days after infection by strain JF1 was assayed by differential interference contrast light microscopy (DIC). **B.** Maize tissue three days after infection by JF1 Δ *znf22* strain was assayed by DIC. **a.** Maize tissue three days after infection by JF1 strain was assayed by epifluorescence (GFP) microscopy. **b.** Maize tissue three days after infection by JF1 Δ *znf22* strain was assayed by epifluorescence (GFP) microscopy. Bar= 10 μ m for all panels.

All these deletion mutants were further examined both in culture (YEPS_L medium) and *in planta*. However, neither a morphology change nor an obvious phenotype could be detected. Also, no obvious influence on tumor formation could be found in these deletion mutants.

In addition, Northern blot analysis was performed to verify the results from fluorescence microscopy. For this purpose, RNA was isolated from five-day-old

plant tumors. The ^{32}P -labeled *eGFP*, *mig2-5*, *mig2-2* and *mig2-6* DNA fragments were used as probes for the Northern blot analysis to detect the expression levels of these genes in these mutant strains five days after plant inoculation.

Similar to the results from the fluorescence microscopy, only the *znf22* deletion mutant JF1 $\Delta znf22$ showed a significant difference in the *mig2-5* promoter activity compared to the wild type strain JF1. While no *eGFP* and *mig2-5* signals could be detected for the *znf22* deletion mutant strain, *mig2-2* and *mig2-6* were still expressed. Although, expression of these genes was somewhat reduced compared to strain JF1, this appeared to be within the variation. For the remaining *znf* gene deletion strains, no drastically diminished signals could be found. Interestingly, in the *znf23* deletion strain, expression of *eGFP*, *mig2-5*, and *mig2-6* appeared stronger than in the other Δznf mutants (**Fig.7**).

Taken together, *znf22* is required to activate the *mig2-5* promoter *in planta*. I therefore refer to Znf22 as putative positive regulator for *mig2-5* and termed it Mzr1 (*mig* zinc finger regulator). However, I could not exclude the possibility that Mzr1 was also involved in regulating the remaining *mig* genes. It is also interesting whether additional proteins are involved in *mig2-5* activation. Since *mig2-2* and *mig2-6* were still expressed in the absence of *znf22*, at least for these genes there should be other proteins to be involved in their activation after plant inoculation.

Figure 7. Expression analysis of *mig* genes in the different *U. maydis znf* deletion mutants.

RNA was prepared from infected plant tissue five days after inoculation. Each gel was loaded with comparable amounts of the same RNA preparations. The Northern blots were probed with ^{32}P -labeled gene-specific fragments of the *mig2* and *eGFP* genes. Staining with methylene blue reflects the amounts of total RNA loaded (28s, 8 μg).

2.3 Overexpression analysis

2.3.1 *mig2-5* promoter requirement for Mzr1 (Znf22)

Due to the identification of Mzr1 (Znf22) as an essential factor for *mig2-5* promoter activation *in planta*, two questions arise: can Mzr1 if overexpressed induce *mig2-5* promoter activation under culture conditions? Are the 5'-CCA-3' elements previously identified in the *mig2-5* promoter (Farfsing *et al.*, 2005) required for the *mig2-5* regulation by Mzr1?

To answer these two questions, the plasmid pCZ22v was generated, in which expression of the *mzr1* ORF was controlled under the carbon source-regulated *crg1* promoter (P_{crg1} ; Bottin *et al.*, 1996). A nourseothricin (*nat*) resistance cassette (Müller *et al.*, 1999) was used as selectable marker for *U. maydis*. Subsequently, the linearized plasmid was ectopically integrated into the genomes of strains JF1, JT3, JS7, JS10, JS11 and JS12. These strains had been constructed on the basis of the JF1 strain (Farfsing *et al.*, 2005). In strain JT3, the 870-bp *mig2-5* promoter fragment had been shortened to 240 bp; in strain JS7, the three regions box I (-130 to -120), box II (-155 to -139), and box III (-189 to -173) were substituted; in strain JS10, three of the 5'-CCAMC-3' motifs were substituted; in strain JS11, the region between position -233 to -225 had been replaced; in strain JS12, six 5'-CCA-3' motifs within positions -215 to -169 were substituted by the sequence 5'-GTC-3'. Next, PCR was performed using primers against the *crg1* promoter and the *mzr1* (primer pair PCRG/Z22b) to confirm the integration of the *crg1* promoter-*mzr1* construct in *U. maydis* transformants. Those transformants which conferred correct PCR products were selected for further analysis.

To determine the expression levels of *mzr1*, the generated JF1/*pcrg1-z22*, JT3/*pcrg1-z22*, JS7/*pcrg1-z22*, JS10/*pcrg1-z22*, JS11/*pcrg1-z22* and JS12/*pcrg1-z22* strains were incubated in complete medium containing 1% arabinose (CM/Ara, for *crg1* promoter induction) for about 15 h until an OD₆₀₀ of 0.5-0.8 was reached. RNA was prepared and hybridized with a ³²P labeled *mzr1*

probe to examine *mzr1* expression levels in JF1 and JF1 promoter mutant strains. In each strain, the three transformants, which showed the strongest *mzr1* expression levels were selected for further analysis to determine the *mig2-5* promoter activity. These selected transformants were incubated under the same conditions as described above. RNA was prepared and hybridized with a ³²P labeled *eGFP* fragment to examine *eGFP* expression in these strains after *mzr1* induction in CM/Ara. Subsequently, RT-PCR was performed to verify *mzr1* and *ip* expression levels in these strains using primer combinations.

Northern hybridization showed that *eGFP* was strongly upregulated after *mzr1* expression in strain JF1 under culture conditions. This revealed that *mzr1* expression under culture condition was sufficient to induce *mig2-5* promoter activity in strain JF1. For the JT3 strain, *mzr1* expression could still induce the expression of *eGFP*. However, the *eGFP* expression in JT3 was weaker than in the strain JF1. This confirmed previous analysis showing that the shortened 240-bp *mig2-5* promoter could still be activated by Mzr1 in culture (Farfsing *et al.*, 2005). In the JS7 strain, almost no *eGFP* signal was detectable. This showed that substitutions of the three regions box I (-130 to -120), box II (-155 to -139), and box III (-189 to -173) abolished the *mig2-5* regulation after *mzr1* expression in culture. This confirmed previous analysis showing that GFP fluorescence in planta was almost abolished in strain JS7 (Farfsing *et al.*, 2005). GFP could still be induced in strain JS10, which corresponding to previous result showing that substitution of three CCAMC motifs (positions from -205 to -202, -189 to -186, -172 to -167) only partially diminished *mig2-5* promoter activity in strain JS10 after inoculation. In contrast, no *eGFP* signal could be detected for the mutant strain JS12. This proved that the six 5'-CCA-3' motifs deleted in strain JS12, which were required for *mig2-5* promoter activity *in planta* (Farfsing *et al.*, 2005), were crucial for the *mig2-5* regulation by Mzr1. In addition, Jan Farfsing's result showed that the substitution in strain JS11 had only a limited effect on GFP fluorescence *in planta*. However, *eGFP* expression was drastically reduced in the strain JS11 after *mzr1* overexpression under culture conditions (**Fig.8**), indicating

that activities via Mzr1 require this element (box IV; Farfsing *et al.*, 2005).

Taken together, my results document that the six 5'-CCA-3' motifs (-215 to -213, -204 to -202, -196 to -194, -190 to -188, -183 to -181, and -171 to -169) that were required for the *mig2-5* promoter activity *in planta* were also crucial for the Mzr1 function under culture conditions.

Figure 8. *mzr1* overexpression analysis.

A. Distribution of repetitive motifs in the *mig2-5* promoter from -240 to -119. Elements matching the consensus 5'-CCAMC-3' are denoted by arrows. CCA base triplets are boxed in light gray. The two inverted repeats of box IV are framed (depiction from Farfsing *et al.*, 2005). **B.** Schematic representation of the various promoter substitution constructs and their activities in the respective transformant 4 days after inoculation. Relative green fluorescent protein (GFP) activities *in planta* were evaluated by microscopy and are indicated by + and - symbols, where - means no detectable GFP fluorescence and + to +++ = increasing fluorescence levels from faintly to brightly fluorescent (depiction from Farfsing *et al.*, 2005).

C. eGFP transcript levels in culture were determined by Northern blot analysis using RNA from strains grown in liquid CM/Ara and a ^{32}P -labeled *eGFP* fragment. Staining with methylene blue reflects the amounts of total RNA loaded (10 μg). *mzr1* and *ip* specific primers were used in RT-PCR (28 cycles) for comparison of *mzr1* and *ip* gene expression levels between independent transformants for each construct. The primer pair YZ7/YZ20 was used for the *mzr1* expression confirmation; primer pair CBS1/CBS2 was used for the *ip* gene.

2.3.2 Mzr1 specificity for *mig* regulations

Based on the finding that Mzr1 can induce the *mig2-5* promoter activity, I addressed specificity of Mzr1. For this purpose, I screened the *U. maydis* genome for related zinc finger proteins. In addition, the C2H2 zinc finger gene *biz1* (Flor-Parra *et al.*, 2006) was involved in this analysis. It has been shown in an independent study that *biz1* overexpression is able to induce expression of *mig2-4*, *mig2-5* and *mig2-6* (M. Vranes and J. Kämper, unpublished).

After comparison of C2H2 zinc-fingers of *U. maydis* Znf proteins, it was found that the C2H2 zinc-fingers of Znf7, Znf12 and Znf23 are very similar to Biz1 or Mzr1 (Fig.9).

Figure 9. Comparison of zinc finger motifs.

Amino acid alignment of the zinc finger domain. Cys residues are marked with red color; His residues are marked with blue color.

To investigate the influences of *znf7*, *biz1*, *znf12* and *znf23* to *mig* gene expression, JF1/*pcrg1-z7*, JF1/*pcrg1-biz1*, JF1/*pcrg1-z12* and JF1/*pcrg1-z23* *U. maydis* strains were constructed based on plasmid pCZ7, pCZ8, pCZ12 and pCZ23, in which

expression of *znf7*, *biz1*, *znf12* and *znf23* is controlled under the carbon source-regulated *crg1* promoter. PCR was performed to confirm the integration of the *crg1* promoter-*znf* constructs in *U. maydis* transformants using primers against the *crg1* promoter and the *znf* genes. Primer pairs PCRG/Z7b, PCRG/Z8b, PCRG/Z12b, PCRG/Z22b, and PCRG/Z23b were used for *znf7*, *biz1*, *znf12*, *mzr1*, and *znf23* genes individually. PCR products of the expected size could be obtained only for those transformants, in which the correct integration took place.

To determine the expression levels of these target genes in each independent transformant, each *U. maydis* transformant, together with the strain JF1/*pcrg1-mzr1* described above, was grown in CM/Ara for about 15h until an OD₆₀₀ of 0.5-0.8 was reached. RNA was isolated and used for Northern blot analysis using the ³²P-labeled *znf* gene specific probes. The Northern hybridization results showed that expression levels of each *znf* gene in the different transformants varied (**Fig.10**). From these transformants, JF1/*pcrg1-z7* #1, #3, JF1/*pcrg1-biz1* #2, #3, JF1/*pcrg1-z12* #1, #2, JF1/*pcrg1-mzr1* #1, #3, JF1/*pcrg1-z23* #4, #6 strains showed the strongest gene expression levels. These strains were selected and grown under conditions as described above. RNA was prepared and used for the following Northern blot analysis to detect *mig* gene expression in these strains. RNA from strain JF1 as well as from six day-old plant tumours of plants infected with the FB1xFB2 mixture was used for Northern hybridizations as negative and positive controls respectively.

Northern blot analysis showed that both *biz1* and *mzr1* overexpression could induce expressions of *mig1*, *mig2-5*, and *mig2-6*. However, Biz1 and Mzr1 play different roles in *mig* gene regulation (**Fig.11**). Mzr1 appeared more specific for *mig2-5* than for *mig1* or *mig2-6*. In contrast, Biz1 was more important for the *mig1* and *mig2-6* induction. For *mig2-1* and *mig2-2*, no signal could be detected in these *U. maydis* strains after either *mzr1* or *biz1* inductions. Very faint *mig2-5* and *mig2-6* signals were detected in the *znf7* overexpression strains. This illustrated that Znf7 could only weakly influence the *mig2-5* and *mig2-6* activities. In addition, *mig2-5* and *ip* expression levels in these strains were tested by RT-PCR

analysis. The RNA prepared for the Northern analysis was used as template after reverse transcription. Primers used for *mig2-5* and *ip* were the same as described above (see **Fig.10**). This showed similar levels of *ip* expression, except for the lane showing *ip* level in infected plant tissue, as expected. Furthermore, the weak *mig2-5* signals in the *znf7* overexpression strains could be confirmed.

Figure 10. Expression analysis of *m zr1*, *biz1*, *znf7*, *znf12* and *znf23*.

Transcription levels of each *znf* gene in individual transformants were determined by Northern blot analysis using RNA from strains grown in liquid CM + 1% arabinose. Northern blots were probed with ^{32}P labeled *znf7*, *biz1*, *znf12*, *m zr1* and *znf23* fragments. Staining with methylene blue reflects the amounts of total RNA loaded (9 μg). The red marked strains were used for further analysis.

Taken together, overexpression of *m zr1* could induce *m ig1*, *m ig2-5* and *m ig2-6* expression under culture conditions. Furthermore, Mzr1 was more specific for the *m ig2-5* regulation. Biz1 could also induce transcriptional activation of *m ig1*, *m ig2-5* and *m ig2-6* in culture. Znf7 could weakly induce *m ig2-5* and *m ig2-6* expression. In conclusion, together with expression in promoter mutant strains (see above), this underlines the specificity of Mzr1 in activating the *m ig* gene promoters. However, regulators for *m ig2-1* and *m ig2-2* genes remain unknown.

Figure 11. Overexpression analysis of zinc finger genes.

mig transcription levels in culture were determined by Northern blot analysis using RNA from strains grown in liquid CM/Ara. RNA was isolated from five day-old tumors infected with strains FB1xFB2. This served as positive control. RNA prepared from the wild type strain JF1 grown in liquid CM/Ara was used as negative control. Northern blots were probed with ³²P labeled *mig1*, *mig2-1*, *mig2-2*, *mig2-5* and *mig2-6* fragments. Staining with methylene blue reflects the amounts of total RNA loaded (9 µg). The *mig2-5* and *ip* specific primers were used in RT-PCR (32 cycles) for gene expression level determinations in independent transformants of each construct.

2.3.3 Relationship between Mzr1 and Biz1

The above results showed that expression of both *mzr1* and *biz1* could induce *mig* gene expression. To determine the relationship between Mzr1 and Biz1 for *mig* regulation, two overexpression strains JF1 Δ *mzr1*/*pcrg1-biz1* and SG200 Δ *biz1*/*pcrg1-mzr1* were constructed: the *crg1* promoter-*biz1* fusion was ectopically integrated into strain JF1 Δ *mzr1* on the one side, and the *crg1-mzr1* fusion was integrated into the *cbx* locus of strain SG200 Δ *biz1* on the other side. To confirm

the sequence insertions into the *U. maydis* genome, PCR analysis was performed using a primer against the *crg1* promoter and gene specific primers against the *mzr1* construct (PCRG/Z22b) and the *biz1* construct (PCRG/Z8b), respectively.

Each five individual strains, which showed the expected PCR products, were selected for subsequent Northern hybridization to demonstrate *mig2-5* expression. To induce expressions of *biz1* and *mzr1*, the selected *U. maydis* strains were grown in CM/Ara for 15h to an OD₆₀₀ of 0.5-0.8. Wild type strains JF1 and SG200 were grown under the same conditions as controls. RNA was prepared and used for the following Northern hybridizations. For *biz1* overexpressing strains, a ³²P-labeled *eGFP* specific DNA fragment was used as probe. A ³²P-labeled *mig2-5* fragment was used as probe for *mzr1* expression strains. To verify expression of *mzr1* or *biz1* in all *U. maydis* transformants, RT-PCR was performed using *biz1* and *mzr1* specific primers and the same RNA utilized for the Northern analysis (as **Fig.12**).

The Northern blot analysis showed that in the *mzr1* deletion strains, the *mig2-5* promoter could be activated after *biz1* overexpression. Interestingly, for the *biz1* deletion strains, no *mig2-5* signal could be detected after *mzr1* overexpression. RT-PCR analysis confirmed comparable expression of *biz1* or *mzr1* in these strains (**Fig.11**).

In summary, Biz1 could induce *mig2-5* promoter activity in the absence of Mzr1, whereas *mzr1* expression in the *biz1* deletion mutant could no longer induce *mig2-5* promoter activity, demonstrating that Mzr1 requires Biz1 for *mig2-5* induction.

Figure 12. Overexpression analysis in *biz1* and *m zr1* deletion mutants.

mig2-5 and *eGFP* expression levels in culture were determined by Northern blot analysis using RNA from strains grown in liquid CM/Ara. RNA isolated from strains JF1/*pcrg1-biz1* and JF1/*pcrg1-m zr1* grown in liquid CM/Ara was used as positive control, denoted with wt, respectively. Northern blots were probed with ^{32}P -labeled *mig2-5* and *eGFP* fragments. Staining with methylene blue reflects the amounts of total RNA loaded (10 μg). *m zr1* and *biz1* specific primers were used in RT-PCR (28 cycles) for gene expression confirmation in independent transformants for each construct. Primer pair YZ22/YZ23 (see Table7) was used for *biz1* and YZ7/YZ20 (see Table7) was used for *m zr1*.

2.3.4 Phenotype of *m zr1* overexpression strains

Recently, it has been shown that *U. maydis biz1* deletion mutants have a severe penetration defect upon inoculation of maize plants. The few hyphae that had penetrated could not proliferate *in planta*. Thus, the sexual development was blocked (Flor-Parra *et al.*, 2006). My results indicated that Mzr1 requires Biz1 for *mig2-5* induction. Since both Mzr1 and Biz1 obviously regulate the same promoter, it was interesting to know whether *m zr1* overexpression could compensate, at least partially, the pathogenicity of *biz1* deletion strains. Furthermore, it was also confirmed that the *mig2-5* promoter activity was strongly reduced in *m zr1* deletion strains after plant inoculation. Therefore, another interesting question was whether *m zr1* overexpression in strain JF1 Δ *m zr1* could

induce *mig2-5* promoter activity *in planta* to a high level.

To answer these questions, *U. maydis* strains JF1 Δ *mzr1*/*potef-mzr1*, JF1/*potef-mzr1* and SG200 Δ *biz1*/*potef-mzr1* were generated, in which the *mzr1* ORF was linked to the constitutive *otef* promoter (Spellig *et al.*, 1996). For the generation of strain SG200 Δ *biz1*/*potef-mzr1*, the *otef* promoter linked *mzr1* ORF was integrated into the *cbx* locus of strain SG200 Δ *biz1*. Integration of the construct was confirmed by Southern blot using a ³²P-labeled *cbx* DNA fragment. Those transformants, which produced two *cbx* linked fragments after BamHI digestion, were selected for further analysis (**Fig.13**). Integration of the constructs into the JF1 Δ *mzr1* and JF1 strains was confirmed by RT-PCR using primer pair JF255/Z22b. Next, the selected JF1 Δ *mzr1*/*potef-mzr1* and JF1/*potef-mzr1* strains, together with the wild type strain JF1, were cultivated in YEPS_L medium for 15 hours for subsequent RNA isolation to confirm expression of the *mzr1* and *ip* genes by RT-PCR. Primer pairs YZ7/YZ20 and CBS1/CBS2 were used for *mzr1* and *ip* gene detection.

This showed that *mzr1* was strongly expressed in these transformants relative to strain JF1 (**Fig.14**). Next, the selected strains were incubated for plant inoculation. Astonishingly, the *mzr1* overexpression strains grew very slowly in YEPS_L medium. To address growth in more detail, these strains were incubated in YEPS_L medium for 25 hours to determine the growth rate in comparison to the wild type strain JF1. The OD₆₀₀ values of growing cultures were measured at multiple intervals during the incubation period. The growth curve illustration shows that the *mzr1* overexpression strains grew significantly slower than the wild type strain JF1 under culture conditions (**Fig.15**). As expected, the Δ *mzr1* strain grew comparable to the parental strain.

In addition, the morphologies of these strains after a 12 h incubation period were compared. In these *mzr1* overexpression strains, filamentous cells appeared increased in number compared to the wild type strain JF1 or to the JF1 Δ *mzr1* mutant strain (**Fig.16**). Additionally, the *mzr1* overexpression also formed aggregates.

Figure 13. Southern blot analysis for the SG200 Δ *biz1*/potef-*mzr1* constructs.

The integration of the the *otef* promoter linked *mzr1* ORF into the *cbx* locus of strain SG200 Δ *biz1* was confirmed by Southern blot using a 32 P-labeled *cbx* DNA fragment and genomic DNA from strains grown in YEPS_L medium for 15h. 10 μ g of genomic DNA was loaded for each independent transformant after *Bam*HI digestion. The selected correct transformants (producing two fragments after digestion) are marked in red.

Figure 14. RT-PCR for the detection of *mzr1* expression levels.

mzr1 transcript levels in culture were determined by RT-PCR analysis using cDNA from *mzr1* overexpression strains and strain JF1. Total RNA was isolated from strains grown in YEPS_L. *mzr1* and *ip* specific primers were used in the RT-PCR analysis to determine the *mzr1* and *ip* gene expression during independent transformants for each construct. 26, 28, and 30 represent PCR cycle numbers.

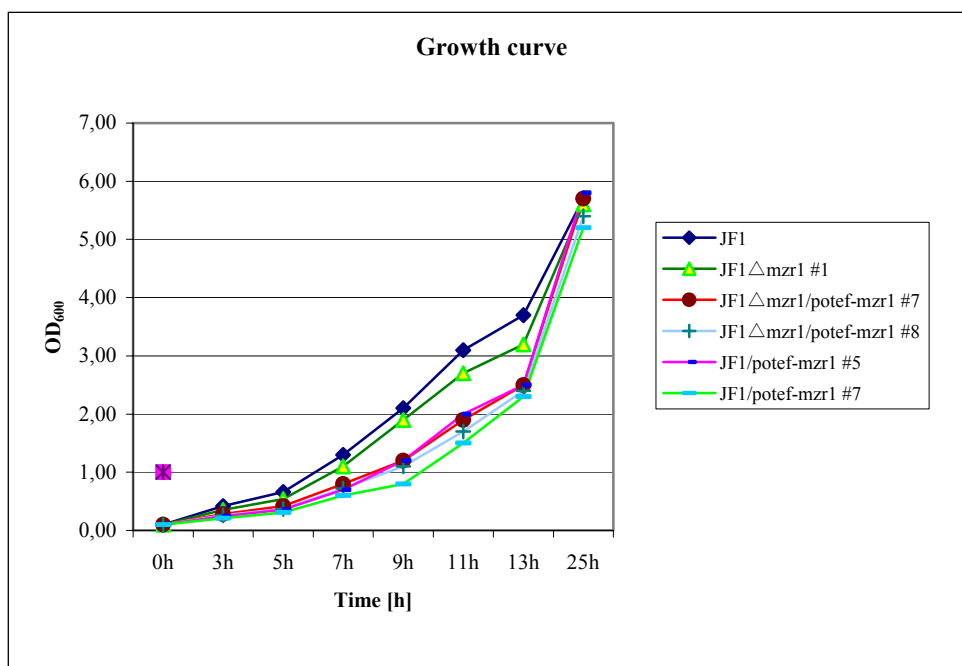

Figure 15. Growth comparison of *mzr1* overexpression strains with wt and *mzr1* deletion strains.

Growth comparison between the *mzr1* overexpression and JF1 strains. All *U. maydis* strains were grown in YEPS_L medium for 15 hours. OD₆₀₀ values for each strain were determined at different time points: 0, 3, 5, 7, 9, 11, 13 and 25 hours after incubation. The starting OD₆₀₀ for each strain was 0.075 adjusted with precultures. Different *U. maydis* strains were marked with different colors in the figure.

Figure 16. Morphology comparison in response to *mzr1* overexpression.

Morphology of different *U. maydis* cells was examined by DIC after a 12 hour incubation period. The starting OD₆₀₀ for each strain was 0.075 adjusted with precultures. Strain types are marked on the top of each figure. Bar= 10 μ m for all panels.

Next, I investigated the behavior of *mzr1* overexpression strains in infected plant tissue. Here, it was particularly interesting to find out whether they were able to complement *biz1* deletion strains with respect to pathogenic development. For this purpose, plants were infected with JF1, JF1 Δ *mzr1*, SG200 Δ *biz1*/*potef-mzr1*, JF1 Δ *mzr1*/*potef-mzr1*, SG200 Δ *biz1* and JF1/*potef-mzr1* strains. In this experiment, JF1, JF1 Δ *mzr1*, SG200 Δ *biz1* strains were used as control. Three days after inoculation, the infected plant tissue was treated with Chlorazole Black E and examined by microscopy. This showed that the fungal penetration occurred for the JF1 and JF1 Δ *mzr1* strains. For the SG200 Δ *biz1*/*potef-mzr1* strain, some *U. maydis* cells had penetrated into plant tissue, but most of them still resided on the plant leaf surface. As expected, fungal penetration was almost completely blocked for the SG200 Δ *biz1* strain. Interestingly, most of the *U. maydis* JF1 Δ *mzr1*/*potef-mzr1* and JF1/*potef-mzr1* cells were floating on the leaf surface without forming penetration structures (**Fig.17**).

Plants were further inspected five days after inoculation to assess tumor formation. This revealed that no tumors could be found for the SG200 Δ *biz1* and SG200 Δ *biz1*/*potef-mzr1* strains. The number of tumors was also drastically diminished for the JF1 Δ *mzr1*/*potef-mzr1* and the JF1/*potef-mzr1* strains compared to the strain JF1. On the other hand, no obvious difference could be detected for tumor formation in the JF1 Δ *mzr1* strain compared to strain JF1 (**Table 3**).

Taken together, *mzr1* overexpression apparently influenced *U. maydis* morphology under culture conditions; more filamentous cells were observed. In addition, *mzr1* overexpression decreased the growth rate of *U. maydis* cells in culture, and could also interfere with the efficiency of plant infection as assessed from reduced penetration and tumor formation. This may explain why *mzr1* is hardly expressed in culture, but is strongly upregulated *in planta* (see **Fig.4**).

Figure 17. Microscopical examination for infected plant tissue three days after inoculation.

Infected plant tissue was examined by DIC microscopy three days after inoculation. Infected plant leaves were cut and stained with Chlorazole Black E (see Materials and Methods). Strains used are indicated on top of each panel. Bar= 10 μm for all panels.

Table 3. Examination of infected plants

Strains	Infected plants	Tumor formation	Percentage
JF1	18	8	44%
JF1 Δ mzr1	19	6	32%
JF1 Δ mzr1/potef-mzr1	45	6	13%
JF1/potef-mzr1	44	5	11%
SG200 Δ biz1	21	0	0
SG200 Δ biz1/potef-mzr1	23	0	0

Maize plants were inoculated with the *U. maydis* indicated on the left. Tumor formation is determined five days after inoculation.

2.4 DNA-protein interaction *in vitro*

All results obtained thus far had pointed out that Mzr1 was involved in *mig* gene regulation: *mzr1* overexpression could induce *mig* gene expression in culture, and *mig2-5* expression was drastically decreased in the *mzr1* deletion strain after plant infection. All these findings suggested that Mzr1 acts as a positive regulator for *mig* genes. However, the question remained whether the *mig* genes were directly regulated by Mzr1; alternatively Mzr1 could induce expression of regulator(s) of *mig* genes. In the latter case, Mzr1 would be an indirect regulator. To address whether Mzr1 is a direct regulator for *mig2-5*, I investigated the interaction between the Mzr1 protein and the *mig2-5* promoter using the electrophoretic mobility shift assay (EMSA) technique.

The EMSA technique is based on the fact that protein-DNA complexes migrate more slowly than free DNA molecules when subjected to non-denaturing polyacrylamide or agarose gel electrophoresis (Hendrickson *et al.*, 1985; Revzin, 1989). Because the rate of DNA migration is shifted or retarded upon protein binding, this assay is also denoted as gel shift.

EMSA can be used qualitatively to identify sequence-specific DNA-binding proteins (such as transcription factors) and, in conjunction with mutagenesis, to identify the important protein binding sequences within a given gene's upstream regulatory region. EMSA can also be utilized quantitatively to measure thermodynamic and kinetic parameters (Fried *et al.*, 1981; Garner *et al.*, 1981; Fried *et al.*, 1984; Fried, 1989).

2.4.1 *U. maydis* cell extracts for DNA binding

One advantage to investigate DNA-protein interactions by EMSA is the ability to resolve complexes of different stoichiometry or conformation. Another major advantage is that the source of the protein used for DNA-binding may be a crude nuclear or whole cell extract rather than a purified preparation, which has been

utilized successfully for *U. maydis* research (Kotani *et al.*, 1993; An *et al.*, 1997). I initially utilized *U. maydis* cell extracts as the DNA-binding protein source for EMSA. *mzr1* and *biz1* overexpression strains previously described (JF1/*pcrg1-mzr1*, JF1/*pcrg1-biz1*) were incubated in CM/Ara medium. The strain FB1 was incubated under the same conditions as a negative control. The protein preparation was performed according to a standard method described below (preparation of *U. maydis* cellular extracts followed the method described in Materials and Methods)

A 500-bp *mig2-5* promoter fragment isolated from plasmid pUMa13 was end-labeled with ^{33}P dCTP. The labeled 500-bp *mig2-5* promoter fragment was mixed with protein extracts from strains overexpressing either Mzr1, Biz1, or the Mzr1/Biz1 mixture individually. After gel running, no clearly shifted band was detectable on the gel (**Fig.18**). To enrich the DNA-binding fraction, the crude protein extract was purified by heparin affinity chromatography for subsequent EMSA under the same conditions. However, the same negative result was obtained even in the presence of 10 μg protein.

Figure 18. EMSA with crude extracts of *mzr1* and *biz1* overexpression strains

EMSA with crude protein extracts and a 500-bp *mig2-5* promoter fragment. Crude proteins extracts were prepared from FB1, JF1/*pcrg1-mzr1* and JF1/*pcrg1-biz1* strains grown in CM/Ara medium for 15 hours. The 500-bp *mig2-5* promoter fragment was end labeled with ^{33}P dCTP and then incubated with the crude protein extracts from strains FB1, JF1/*pcrg1-mzr1*, JF1/*pcrg1-biz1* and the JF1/*pcrg1-mzr1*/JF1/*pcrg1-biz1* mixture individually. 20 and 50 represent 20 μg and 50 μg protein mixed with DNA.

2.4.2 *mzr1* expression in *E. coli*

Based on the negative EMSA result obtained with crude or partially purified protein fractions, a strategy was designed to purify Mzr1. For this purpose, the plasmid pBAD102/D-TOPO was selected as cloning vector, which can be used directly for insertion of a blunt-ended PCR product possessing a 5'-CACC overhang. This vector contains coding sequences for a C-terminal His-tag (6xHis) and a N-terminal thioredoxin for increased translation efficiency and solubility of heterologous proteins. The His-tag fusion was used for detection of protein expression and for purification of the recombinant fusion protein. The arabinose-inducible *araBAD* promoter initiates the gene expression in this plasmid.

In order to express the Mzr1 protein successfully in *E. coli*, I selected a truncated N-terminal portion containing the zinc-finger domains as cloning target (**Fig.19**). The zinc finger domain of C2H2 proteins has been shown to be sufficient for establishing specific DNA contacts (Pavletich and Pabo, 1991). The DNA fragment was amplified by PCR using the cDNA from strain JF1/*crg1-mzr1* previously prepared for RT-PCR analysis (**Fig.8**). A 1102 bp PCR product (sequence of truncated *mzr1* + CACC), in which the 80 bp intron of *mzr1* gene (positions from 559 to 639) had been deleted, was ligated into the pBAD102/D-TOPO vector. The resulting plasmid pTOPO-Z22 was transformed into *E. coli* TOPO10 cells. The generated *E. coli* strain TOPO10-Z22 was used as host strain for subsequent protein expression and purification assays.

To identify the proper expression conditions, the selected *E. coli* strain TOPO10-Z22 was grown under different arabinose concentrations (0, 0.0002%, 0.002%, 0.02% and 0.2%). After 14 hours of incubation, the *E. coli* cells were cracked using a French-Press. Both soluble and insoluble fractions were collected for Western blot analysis using an anti-His (C-terminal) antibody.

The result showed that a 0.0002% arabinose concentration (in the absence of glucose) was sufficient to induce expression of the fusion protein, which could be

obtained from the soluble fraction of cell extracts. However, most of the Mzr1 fusion protein was detected in the insoluble pellet fractions (**Fig.20**). This implied that the concentrated Mzr1 fusion protein formed inclusion bodies in *E. coli* cells. For further purifications, I selected the 0.0002% arabinose concentration.

Figure 19. The truncated N-terminal portion of Mzr1 used for cloning (obtained from <http://www.broad.mit.edu>).

The truncated N-terminal portion of Mzr1 expressed in *E. coli*. The zinc finger domains are denoted. Cys residues of the zinc fingers are marked with red color; His residues are marked with blue color.

To confirm these results, the *E. coli* strain TOPO10-Z22 was grown in LB medium containing 0.0002% arabinose for 14 hours and cracked using a French-Press. After centrifugation, the supernatant fraction was collected for the Western blot analysis to confirm the expression of the soluble fusion protein (~ 63 kD, **Fig.21**). The Western blot result showed that 0.0002% arabinose could be used successfully for the preparation of the soluble Mzr1 fusion protein in *E. coli*.

Figure 20. Determination of the concentration of arabinose for inducible protein expression.

Western blot analysis for the detection of the Mzr1-His fusion protein. Proteins used for the Western blot analysis were prepared from *E. coli* TOPO10-Z22 strains grown in LB medium, with different arabinose concentrations from 0 to 0.2%. Both soluble and insoluble fractions were collected for the Western blot analysis using an anti-His antibody. Arabinose concentrations are marked on top. 80 μ g protein was loaded on each lane of the gel.

Figure 21. Western blot analysis for the determination of the Mzr1-His fusion protein.

Western blot analysis for the detection of crude Mzr1-His fusion protein. Proteins used for the Western blot were prepared from *E. coli* TOPO10-Z22 strains grown in LB medium containing 0.0002% arabinose. The soluble supernatant was collected after centrifugation for the Western detection by the anti-His antibody. Protein markers were used to determine the protein size of the fusion protein (~ 63 kD). The two lanes on the gel are from the same preparation (80 μ g fusion protein).

To obtain the purified Mzr1 fusion protein based on the His-tag in the constructed plasmid pTOPO-Z22, the Ni-NTA Spin Kit was used. The high affinity of Ni-NTA resins for His-tagged proteins is due to the specificity of the interaction between histidine residues and immobilized nickel ions held to the NTA resin. After binding of His-tagged proteins to the NTA resin, the NTA resin was first washed and then eluted. Subsequently, the collected eluate was loaded on a PD-10 column (to desalt) to prepare the purified Mzr1 fusion protein used for EMSA studies.

To examine that the fusion protein is present in the eluate, the eluate was applied to SDS-PAGE gel for Western blot analysis using the anti-His antibody. The Mzr1 fusion protein of the expected size could be detected in the Western blot confirming the existence of the His-tagged fusion proteins after protein purification (**Fig.22**). The purified Mzr1 fusion protein was finally used for the EMSA studies.

Figure 22. Western blot analysis for the Mzr1 fusion protein after purification.

Western blot analysis for the detection of the purified Mzr1-His fusion protein. Proteins used for the Western blot were prepared from *E. coli* strain TOPO10-Z22 grown in LB medium containing 0.0002% arabinose. The soluble supernatant (after centrifugation) was collected and purified by Ni-affinity chromatography. The collected protein was desalted using a PD-10 column and was then used for the Western detection using the anti-His antibody. Protein markers were used to determine the protein size (marked on right). 7 μ g of fusion protein was loaded onto the gel.

2.4.3 DNA binding analysis with purified Mzr1 fusion protein

Previous work had demonstrated that 5'-CCA-3' motifs located in the *mig2-5* promoter are required for *mig2-5* promoter activity (Farfsing *et al.*, 2005). It was thus presumed that CCA-containing sequences are crucial for binding by Mzr1. For EMSA, I initially used the 200-bp *mig2-5* promoter fragment from positions -120 to -320 (**Fig.23**). This promoter fragment contains 16 CCA/TTG motifs and was sufficient to induce full *mig2-5* promoter activity (Farfsing *et al.*, 2005).

This 200-bp *mig2-5* promoter fragment prepared from pJM19 (see Materials and Methods) was end-labeled with ^{33}P dCTP for EMSA in the presence of the purified Mzr1 protein (see above). EMSA revealed several distinct bands (**Fig.24**). The intensity of shifted bands increased with increasing protein concentrations of the Mzr1 fusion protein and a second presumed DNA-protein complex could be detected when 1 μg of fusion protein was used (complex II in **Fig.24**).

Figure 23. The *mig2-5* promoter sequence position from -1 to -321.

A 200bp *mig2-5* promoter fragment positions from -120 to -320 was used for EMSA. CCA /TTG sequences are marked in orange.

To address specificity of the shifted bands, EMSA was performed in the presence of the unlabeled competitor fragment. For this purpose, the same 200-bp *mig2-5* promoter fragment prepared from pUMa13 using PCR was used as binding

competitor without labeling. Excess of unlabeled DNA competitor was mixed with the Mzr1 protein prior to addition of the labeled DNA fragment. If the DNA-protein binding is specific, the majority of the protein should be bound by the excess of unlabeled DNA and thus there should be only little protein left for binding to the radioactively labeled DNA fragment. To examine the DNA-protein binding specificity, I used 45, 150 and 300-fold molar excess of unlabeled DNA competitor for the binding assay. Along with increasing concentrations of the DNA competitor, the intensity of the shifted bands decreased. For the 300-fold molar excess of the unlabeled DNA fragment, almost no shifted band could be detected (**Fig.24**).

Figure 24. EMSA using the purified Mzr1 protein and a 200-bp *mig2-5* promoter fragment.

EMSA using the purified Mzr1 fusion protein and a 200-bp *mig2-5* promoter fragment (positions from -120 to -320). A 200-bp *mig2-5* promoter fragment was end labeled with ^{33}P dCTP and was then incubated with the purified Mzr1 fusion protein. 0, 0.25 μg , 0.5 μg and 1.0 μg of the Mzr1 protein preparation was added separately. For the competition analysis, excess of the unlabeled same *mig2-5* promoter fragment (45-fold, 150-fold and 300-fold) was mixed with 1 μg of Mzr1 protein before the radioactively labeled DNA fragment was added (see Materials and Methods).

This result provided evidence that the truncated Mzr1 fusion protein could specifically bind to the 200-bp *mig2-5* promoter fragment *in vitro*. The second shifted band, the presumed DNA-protein complex II, possibly comes from

multiple binding of Mzr1 to the *mig2-5* promoter region due to many potential CCA-containing sites. Based on the finding that the mutated *mig2-5* promoter construct, which is substituted in six CCA motifs, in strain JS12 could not be activated by *mzr1* overexpression (**Fig. 8**), it was interesting to know whether the Mzr1 fusion protein was able to bind to the 200-bp promoter fragment isolated from plasmid pJS12 containing the CCA substitutions (within positions –215 to –169, see **Fig. 25**).

Figure 25. Mutated *mig2-5* promoter region in plasmid pJS12.

The 200bp mutant *mig2-5* promoter fragment (positions from –120 to –320) was used for EMSA. Six of CCA /TGG sequences were replaced by GTC (marked in blue).

Although, in plasmid pJS12 only six of the CCA motifs had been substituted within the 870 bp *mig2-5* promoter region, and thus many additional sites were left, it has been shown by J. Farfsing (Farfsing *et al.*, 2005) and in this study that this promoter could no longer be activated. Therefore, I used this fragment for the next EMSA study. For this purpose, 1 µg of the Mzr1 fusion protein was mixed with the ³³P end-labeled 200-bp mutant *mig2-5* promoter fragment. The ³³P end-labeled 200-bp wild-type *mig2-5* promoter fragment was used as control. The DNA competitor used for the 200-bp mutant *mig2-5* promoter fragment was prepared by PCR using the primer pair YZ70/YZ71 and pJS12 as template. EMSA revealed that for the wild-type *mig2-5* promoter fragment, the same shifted bands (complex I and II) were obtained as expected. Furthermore, one additional shifted band (DNA-protein complex III) appeared in this experiment (**Fig.26**).

This possibly arose from multiple protein binding. In contrast, for the 200-bp mutant *mig2-5* promoter fragment, only one shifted band (DNA-protein complex I) could be clearly detected by EMSA. Interestingly, this band also decreased to a lower level after addition of a 300-fold molar excess of mutant competitor DNA. This provided evidence that the 200-bp mutant *mig2-5* promoter fragment could also be specifically bound by the Mzr1 fusion protein *in vitro*, however, higher molecular weight complexes appeared reduced.

Figure 26. EMSA using the 200-bp natural and mutant *mig2-5* promoter fragments.

EMSA using the purified Mzr1 fusion protein and the 200 bp wild-type or mutant *mig2-5* promoter fragments (positions from -120 to -320). 200-bp wild-type and mutant *mig2-5* promoter fragments were end-labeled with ^{33}P dCTP and then incubated with 1 μg of the purified Mzr1 fusion protein. For the competition analysis, a 300-fold molar excess of the unlabeled 200-bp wild-type and mutant *mig2-5* promoter fragments (-120 to -320) were mixed with 1 μg of the Mzr1 protein preparation before the radioactively labeled 200-bp wild-type or mutant DNA fragments were added.

It has been shown that six of CCA/TGG motifs within the entire *mig2-5* promoter from positions -320 to -120 were required for *mig2-5* promoter activity (Farfsing *et al.*, 2005). However, the 200-bp mutant *mig2-5* promoter fragment from positions -320 to -120, in which six CCA/TGG motifs had been replaced, could still bind to the Mzr1 fusion protein (see above). This discrepancy might be explained as follows: the six CCA/TGG motifs within the *mig2-5* promoter

between positions –120 and –240 are crucial for *mig2-5* promoter activity but are not essential key positions for Mzr1 binding *in vitro*. In addition, there were still ten CCA/TGG motifs left in the 200-bp mutant *mig2-5* promoter at positions from –319 to –317, –310 to –308, –305 to –303, –285 to –283, –278 to –276, –269 to –267, –247 to –245, –230 to –228, –227 to –225 and –200 to –198 (**Fig.25**); these motifs might take part in protein binding *in vitro*, although they are not sufficient to confer inducible *mig2-5* promoter activity. There is still another possibility: the Mzr1 protein used in the EMSA study was truncated and analyzed *in vitro*; the binding conditions *in vivo* could be different and influenced by other proteins as suggested by the relationship with Biz1 (see Discussion).

The 200-bp wild-type and mutant *mig2-5* promoter fragments were shown to bind to the Mzr1 fusion protein. To further analyze this problem, I performed EMSA with the 120-bp *mig2-5* promoter fragment (from –120 to –240, **Fig. 23**). For control, I selected a 160-bp *mig2-5* promoter sequence from positions –1 to –161 (**Fig. 27B**). This promoter region could not confer high *mig2-5* promoter activity as detected *in planta* (Farfsing *et al.*, 2005).

EMSA was performed using the ³³P end-labeled 160-bp (**Fig. 27B**), 120-bp wild-type and mutant (**Fig. 27A**) *mig2-5* promoter fragments in the presence of 1 µg of the truncated Mzr1 fusion protein as described above.

Again, several shifted signals were detected when the 120-bp fragment was used (**Fig. 28**). Explicitly, for the 120-bp natural fragment, two shifted signals (complex I and II) appeared. These two shifted signals disappeared when 300-fold molar excess of cold DNA competitor was added. For the 120-bp mutant *mig2-5* promoter fragment, only one shifted signal (complex I) could be detected, which also disappeared in the presence of a 300-fold molar excess of cold DNA. In contrast, no shifted band could be detected for the 160-bp control promoter fragment. This proved Jan Farfsing's result that this promoter region cannot confer inducible *mig2-5* promoter activity.

Figure 27. *mig2-5* promoter sequences used for EMSA.

A. The 120-bp mutant *mig2-5* promoter sequence from -120 to -240 was used for EMSA, in which six CCA /TGG motifs were replaced by GTC (marked in blue color). **B.** The 160-bp *mig2-5* promoter sequence from -1 to -161 was used for EMSA as negative control. There are five CCA motifs in this region (marked in red color)

These results provided evidence for specific binding of the truncated Mzr1 fusion protein to the 120-bp *mig2-5* promoter fragment *in vitro*. However, this also showed that upstream CCA motifs not present in the short 120-bp fragment might contribute to binding, although they are not sufficient for promoter activation. In consistence to the result of J. Farfsing (Farfsing *et al.*, 2005), the 160-bp *mig2-5* promoter fragment, which cannot confer inducible *mig2-5* promoter activity, could also not be shifted by Mzr1.

Figure 28. EMSA with the purified His-tagged Mzr1 protein and shorter *mig2-5* promoter fragments.

EMSA with the purified Mzr1 fusion protein. 160-bp (-1 to -161) and 120-bp natural/mutant *mig2-5* promoter (-120 to -240) fragments were end-labeled with ^{33}P dCTP and then incubated with 1 µg of the purified Mzr1 fusion protein. For competition analysis, 300-fold molar excess of unlabeled *mig2-5* promoter fragment (wild-type or mutant) were mixed with 1 µg of the Mzr1 protein preparation before addition of radioactively labeled DNA fragments.

In summary, the truncated Mzr1 fusion protein showed binding activity to the *mig2-5* promoter regions from -120 to -320 as well as from -120 to -240 *in vitro*. Furthermore, evidence could be provided that binding is influenced by the CCA/TGG motifs.

2.5 Mzr1 induced genes in *U.maydis*

2.5.1 Microarray analysis

Based on the finding that the Mzr1 protein was a positive regulator for *mig1*, *mig2-5*, and *mig2-6*, it was interesting to know whether there are additional genes that can be induced by Mzr1. Additional Mzr1 induced genes could be identified by DNA-microarray analysis (K. Auffarth and C. Basse, unpublished). For this purpose, the strain JF1/*pcrg1-mzr1* was incubated in CM/Ara medium for an 8 h period upon transfer from CM/Glu. For comparison, strain JF1 was incubated in parallel. DNA-array analysis showed that *mig2-4*, as well as numerous additional genes were upregulated upon *mzr1* expression (Table 4). Among them, *um01820*, *um10055* and *um01240* were the most strongly upregulated genes besides *mig* genes after *mzr1* expression. Interestingly, many of the identified upregulated genes encode putative secreted proteins (Table 4; C. Basse). Thus, it is intriguing to note that Mzr1 regulates additional genes apart from the *mig* genes, but can induce only a subset of the *mig2* cluster genes, which show a very similar developmental expression pattern (Basse *et al.*, 2002).

Table 4. Microarray analysis for *mzr1* expression (provided from Christoph Basse)

2.5.2 *um01820* is another major target regulated by Mzr1

To further analyse whether *um01820* is similarly regulated as *mig2-5*, Northern blot analysis was performed using the same membrane (see **Fig. 11**) as previously used to assess *mig* gene expression in response to Biz1, Mzr1 and related Znf proteins.

Figure 29. Overexpression analysis for *um01820*

um01820 expression levels induced in the various overexpression strains were determined by Northern blot analysis using RNA from these strains grown in liquid CM + 1% arabinose for 15 h. RNA isolated from five day-old tumors infected with strains FB1xFB2 was used as positive control. RNA prepared from the wild type strain JF1 grown in liquid CM/Ara was used as negative control. Northern blot analysis was probed with a ^{32}P labeled *um01820* fragment. Staining with methylene blue reflects the amounts of total RNA loaded (9 μg).

This analysis revealed that overexpression of both *mzr1* and *biz1* could induce *um01820* expression under culture conditions in a very similar way that observed for *mig2-5* (**Fig. 29**). As expected, neither Znf7, Znf12 nor Znf23 could confer *um01820* expression. In addition, the expression pattern of *um01820* *in planta* was examined after plant inoculation. A similar expression profile was obtained for *um01820* compared to *mig2-5* (**Fig. 30**). This corroborates a similar mode of regulation of *mig2-5* and *um01820*, although they are not clustered.

Figure 30. Expression analysis for *um01820* upon plant infection.

RNA gel blot analysis of *mig2-5* and *um01820* transcript levels during plant infection. Plants were inoculated with a mixture of FB1/FB2 strains and total RNA was extracted from infected parts. For the 12h and 2d-time points, material was collected 0.5-3 cm above ground and 0.5-3 cm below the injection site, respectively. For the 4d, 6d, and 9d-time points, chlorotic or early leaf tumor (4d) and leaf tumor (6d and 9d) tissue was collected between the ligule and >1 cm below the injection site. Filters were hybridised with the ^{32}P -labeled *mig2-5* and *um01820* probes. Methylene blue staining (28S) reflects the amounts of RNA loaded (7 μg).

2.5.3 The role of Mzr1 in host-dependent gene regulation

To verify if the *mzr1* deletion can also influence *um01820* expression *in planta*, maize plants were infected with the JF1, JF1 Δ *mzr1*, and JF1 Δ *znf23* strains. Strain JF1 Δ *znf23* was selected based on the finding that expression of *mig2-5* and *mig2-6* were slightly increased in this strain in comparison to JF1 and other *znf* deletion strains (see Fig. 7). RNA was isolated from host tumor tissue six days after inoculation for Northern blot analysis using the ^{32}P -labeled *mig2-2*, *mig2-5*, and *um01820* probes. As expected from the above results (see Fig. 7), *mig2-2* expression in the three different *U. maydis* strains was comparable. In consistence with my previous investigation, the *mzr1* deletion strain showed a very weak *mig2-5* signal, corroborating the role of Mzr1 for *mig2-5* expression *in planta*. Interestingly, also a strongly decreased *um01820* signal was detected in the *mzr1*

deletion strain compared with the JF1 and JF1 Δ *znf23* strains. This demonstrated that Mzr1 is also required for the transcription of *um01820* in *planta*. Furthermore, the expression levels of *mig2-5* and *um01820* were clearly increased in the strain JF1 Δ *znf23* compared to the wild type strain JF1 (**Fig. 31**). These results suggest that the additional Mzr1-induced genes identified by DNA-array analysis require Mzr1 for high-level gene expression in *planta*.

Figure 31. Expression analysis of *mig* and *um01820* genes in deletion mutants.

RNA was prepared from infected plant tissue six days after inoculation with the JF1 Δ *mzr1*, JF1 Δ *znf23* and wild type JF1 strains. Each gel was loaded with same amounts of the same RNA preparations (14 μ g). The Northern blot was probed with 32 P-labeled *mig2-2*, *mig2-5* and *um01820* fragments. Staining with methylene blue (*28s*) reflects the amounts of total RNA loaded. The signals were quantified and are marked on the bottom of each lane.

3 Discussion

3.1 Summary and outlook

My results have demonstrated that Mzr1 (the C2H2-type zinc finger protein) is a positive regulator for a subset of the *mig* genes. In consistence with such a function, *mzr1* is strongly upregulated after plant penetration, whereas its expression was faintly detectable during axenic growth. Overexpression of *mzr1* could induce the transcriptional activation of the *mig* genes and several other genes (see **Table 4**). In addition, overexpression of *mzr1* was observed to favour formation of filamentous cells under culture conditions and compromised tumor formation. I could show that a truncated Mzr1 protein, which contains both zinc finger domains, could bind to the *mig2-5* promoter *in vitro*, and binding was influenced by CCA/TGG motifs, which are important for promoter activity *in vivo*. In addition, another C2H2-type zinc finger protein, Biz1, was found to be tightly connected to *mig* gene regulation. Overexpression of *biz1* strongly induced expression of the same subset of *mig* genes under culture conditions as induced in response to Mzr1. Moreover, evidence could be provided that the C2H2-type zinc finger protein Znf23, which is related in its zinc finger domains to Mzr1, negatively affects expression of the Mzr1-responsive genes *mig2-5* and *um01820*.

3.2 C2H2 zinc finger regulators

Accurate control of gene expression is important for understanding gene function and for developing therapeutics to treat diseases (Urnou *et al.*, 2002). Transcriptional regulators bearing a C2H2 zinc finger are thought to be confined to eukaryotes; however, recent studies have confirmed their presence in prokaryotes (Bouhouhe *et al.*, 2000). The zinc finger often interacts with specific

DNA sequences in the promoter or enhancer region. Basic and hydrophobic residues in the α -helix of the $\beta\beta\alpha$ structure appear to be the primary determinants of DNA binding, making specific contacts with 2-4 bases in the major groove of the DNA helix (Choo *et al.*, 1997).

Many C2H2 zinc fingers have been shown to interact with RNA and DNA/RNA heteroduplexes with high affinity. Wilms' tumour protein 1 (WT1), a KLF protein that can bind to both DNA and RNA, is thought to play an important role in the maturation of mRNA (Little *et al.*, 1999). In addition, it has been shown that the zinc fingers themselves can be involved in protein-protein contacts: they often interact with other transcription factors (Gregory *et al.*, 1996; Lee *et al.*, 1993; Merika *et al.*, 1995). However, relatively little is known about zinc finger-RNA interactions or about protein-protein interactions involving zinc fingers. What is the structural basis for such contacts? What are the biological roles for these interactions?

Some transcriptional regulators have been described in phytopathogenic fungi. The C2H2 zinc finger transcription factor PacC in *Fusarium oxysporum* is involved in pH sensing and required for virulence (Caracuel *et al.*, 2003). The CREB-like transcription factor CPTF1 in *Claviceps purpurea* is involved in oxidative stress response and virulence influence (Nathues *et al.*, 2004). A pathway-specific transcription factor ToxE is essential for the expression of HC-toxin required for pathogenicity of *Cochliobolus carbonum* (Pedley and Walton, 2001). However, only little has been known on Mzr1 function. In this work I could show that it is required for expression of the *mig* genes. No significant homologous protein could be found in the databases outside the zinc finger domain using blast search (<http://www.ncbi.nih.gov/blast/>).

3.3 Protein-DNA interaction *in vivo*

Protein-DNA binding assays have shown that the truncated Mzr1 fusion protein binds to the *mig2-5* promoter *in vitro* in dependence of the CCA/TGG triplet motifs that are essential for promoter activity. However, the truncated Mzr1 fusion protein could still bind to the CCA mutant promoter, although the mutant *mig2-5* promoter in JS12 was unable to confer inducible promoter activity *in planta* (see **Fig. 8**). This could be explained as follows: 1) the 5'-CCA-3' motifs are important for *mig2-5* promoter activity but are not crucial for protein binding; 2) the CCA motifs left in the mutant promoter sequence are sufficient for protein binding but not enough to activate *mig2-5* transcription; 3) EMSA revealed three shifted bands for the 120-bp and 200-bp *mig2-5* promoter fragments, whereas only one shifted signal could be detected for the mutant *mig2-5* promoter fragment from plasmid pJS12. This suggests that the two additional shifted bands (DNA-protein complex II, III; see **Fig. 26**) that were detected for the native promoter are relevant for the inducible *mig2-5* promoter activity.

This raises the question as to whether Mzr1-DNA interactions occur in the same way *in vivo*. The protein used for EMSA represents the truncated Mzr1 protein, which was expressed in *E. coli* and purified via affinity chromatography. Therefore, I cannot judge whether the entire Mzr1 protein expressed in *U. maydis* confers the same binding specificity.

To investigate the protein-DNA interactions *in vivo*, a new strategy based on chromatin immunoprecipitation was attempted to verify specific binding of Mzr1 to predicted target promoters *in vivo* and will be finished in future. For this purpose, an *U. maydis* strain has been constructed, in which the *crg1* promoter controlled *mzr1-strep-tag* sequence was introduced. The principle of this method is described in **Fig. 32**.

Figure 32. Chromatin immunoprecipitation strategy.

Chromatin immunoprecipitation is performed as follows. Formaldehyde is used for the cross-link of Mzr1-Strep fusion protein to the predicted target promoter in living *U. maydis* cells. Cells are broken open and the chromatin DNA is cut into small fragments. Mzr1-Strep protein binding DNA fragments is linked to pre-blocked protein G agarose beads. Next, immunoprecipitation is performed after addition of anti-*Strep* antibody. Enriched DNA-Mzr1-Strep complex is reverse cross-linked and treated with proteinase K. Finally, the precipitated DNA is used for sequence detection and quantification by PCR.

3.4 The relationship of Biz1-Mzr1 for *mig* gene regulation

Intriguingly, although the zinc finger motifs from Biz1 differ from those of Mzr1 (Fig. 33), both Biz1 and Mzr1 triggered induction of the same subset of *mig2* genes. How can this relationship be explained? Mzr1 needs a low level of Biz1 as existing in strain JF1 due to the presence of compatible *bE/bW* alleles for *mig2-5* regulation under culture conditions, whereas Biz1 can induce *mig2-5* expression in the absence of Mzr1. However, the *mig2-5* promoter activity was very weak in the *mzr1* deletion strain after plant inoculation as judged from Northern blot analysis and GFP fluorescence microscopy. These results implied that the function of Biz1 is different from that of Mzr1 *in planta*. Based on the requirement for

Biz1, it was expected that *mig2-5* could not be expressed in the *biz1* deletion strain after plant penetration. However, this question remains hypothetical because plant penetration is almost blocked completely for *biz1* deletion strains.

Furthermore, the overexpression analysis of *mzr1* and *biz1* has shown that Mzr1 and Biz1 play different roles in *mig* gene regulation (see **Fig. 11**). While Mzr1 is more specific for *mig2-5* than for *mig1* or *mig2-6*, Biz1 contributes more to *mig1* and *mig2-6* induction than Mzr1. This implicates the following question: How do Mzr1 and Biz1 individually contribute to *mig* gene expression?

The interaction between a zinc finger protein and its target DNA is dependent on its amino acid residues. Generally, each zinc finger binds a single zinc ion that is sandwiched between the two-stranded antiparallel β -sheet and the α -helix, producing a compact fold. In this fold, it has been revealed that positions -1, 2, 3, and 6 of the α -helix are important for the base-specific contacts of the zinc finger-DNA binding (Scot *et al.*, 1999). The zinc finger comparison showed that the zinc finger I of Mzr1 and Biz1 share the same amino acid residues at positions 3 and 6, and the zinc finger II possess the same amino acid residues at positions -1, 2, and 6. This suggests that Mzr1 and Biz1 bind to similar DNA sequences.

In fact, only little is known about the relationship between Mzr1 and Biz1 for *mig2-5* regulation. Under culture conditions, Mzr1 needs Biz1 for *mig2-5* induction. Actually, it has been shown that zinc-centered domains can be involved in protein-protein interaction (Matthews and Sunde, 2002). However, the Mzr1 zinc finger domain can bind to the *mig2-5* promoter independently. In addition, it could be shown that Mzr1 resides in the nucleus independently of *biz1* expression (E. Kaya and C. Basse, personal communication). Based on these results, the following possibility for *mig2-5* regulation exist: Biz1 and Mzr1 bind to the *mig2-5* promoter at different regions for the following activation. In this case, I give the following regulation model (**Fig. 34**). Overexpression of *biz1* can independently induce *mig2-5* expression in culture (**Fig. 34B**). Expression of *mzr1* cannot induce *mig2-5* expression in absence of Biz1 because the Mzr1 protein cannot bind to the core promoter of *mig2-5* (**Fig. 34C**). This has been proven by

Figure 34. Model of *mig2-5* regulation by interplay of Mzr1 and Biz1.

A. Binding sites of Mzr1 and Biz1. Mzr1 and Biz1 bind to the enhancer and the core promoter elements of the *mig2-5* promoter individually. **B.** In the *mzr1* deletion strain, expression of *mig2-5* is induced by *biz1* overexpression under culture conditions. **C.** Overexpression of *mzr1* can no longer induce the transcriptional activation of *mig2-5* in the *biz1* deletion strain under culture conditions. **D.** Overexpression of *mzr1* changes the conformation and thus strongly enhances *mig2-5* expression in the presence of Biz1.

3.5 Other possible candidates for *mig* gene regulators

In the deletion analysis of *znf* genes that were selected based on their expression levels *in planta* (see **Fig. 4**), the only gene whose deletion showed a significant decrease for the *mig2-5* expression was *mzr1*. However, for $\Delta znf23$ deletion, I could show that the expression of *mig2-5* and *um01820* was increased compared to the wild type strain JF1 in infected tissue (see **Fig. 7**, **Fig. 31**). The zinc fingers of Znf23 are very similar to that of Mzr1 (see **Fig. 9**). This suggests that Znf23 can also bind to the *mig2-5* promoter. Therefore I conclude that Znf23 acts as a negative regulator of *mig2-5* and *um01820*. In such a scenario, an interplay between Mzr1, Znf23 and Biz1 is conceivable as depicted in the following extension of the previous model (see **Fig. 34**): Znf23 acts as repressor by binding to specific promoter elements of *mig2-5* (enhancer or core promoter), blocking the assembly of Mzr1 or Biz1 required to initiate transcription. Thus, the pattern of transcription of *mig2-5* at a particular time may depend on the balance between Mzr1, Znf23 and Biz1. Both overexpression of *mzr1* and *biz1* may destroy this balance and thus initiate transcription of the *mig2-5* gene; deletion of *znf23* therefore promotes expression of *mig2-5 in planta*. For this model, it is interesting to verify the binding and the binding sites of Znf23 to the *mig2-5* promoter.

Znf7 was considered as another candidate regulator of the *mig2* genes. Comparison of the zinc fingers showed that Znf7 is the closest homolog of Biz1 besides Znf12 (see **Fig. 9**). The present overexpression analysis has shown that Znf7 can confer weak transcriptional activation of *mig2-5* (**Fig. 10**). However, the *znf7* deletion strain showed no significant difference in *mig2-5* activation *in planta*, thus its function might be related to activation of genes different from *mig* and similarly regulated genes.

3.6 The function of Mzr1 induced proteins

Mzr1 confers induction of numerous *mig* genes as well as of additional genes, and furthermore, contributes to expression of some of these genes *in planta* (see **Fig. 31**). This raises the question whether Mzr1-regulated genes have similar functions. Interestingly, the real-time PCR result showed that the expression of many Mzr1-induced genes is strongly upregulated early after plant inoculation (J. Kief, personal communication). This result illustrates that Mzr1-induced genes could have a function *in planta*. This is consistent with the finding that many of these genes encode predicted secreted proteins (see **Table 4**). Um1820 is predicted to be secreted and contains few cysteine residues just as the Mig1 protein. I could explicitly show that *um01820* exhibits an expression pattern very similar to that of *mig2-5*, and that *mzr1* is already ~30-fold upregulated two days after plant inoculation (**Fig. 35**). After plant penetration, expression of all *mig* genes and of *um01820* was kept at a high level until teliospore formation. This suggests that Mzr1-induced genes influence the host interaction until the sexual life cycle is completed. Since neither *mig* genes nor Mzr1 was required for pathogenesis, I assume that this originates from redundant protein functions and from residual gene expression in the $\Delta m z r 1$ mutant.

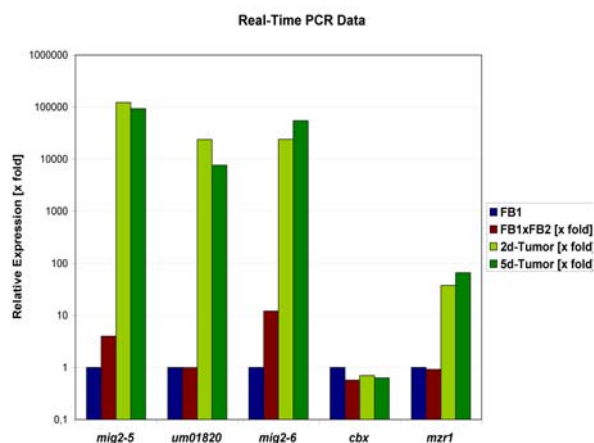

Figure 35. Real-time PCR analysis (provided from Jan Kief).

Expression levels of the *mig2-5*, *mig2-6*, *um01820*, *cbx* and *mzr1* were determined by real-time PCR analysis during different pathogenic development stages. RNA was isolated from four development stages: FB1, FB1xFB2, and plant tissue infected with FB1xFB2 two days and five days after inoculation. Different colors represent the four different stages and are marked on right.

I could show that overexpression of *mzr1* has an influence on the morphology of *U. maydis* cells in culture. Furthermore, pathogenicity of strains overexpressing *mzr1* under the *otef* promoter is reduced (see **Table 3**). *mzr1* is only weakly expressed in culture, but is strongly upregulated *in planta* (see **Fig. 35**). Additionally, I could show that in *mzr1* overexpression strains, plant penetration happened only rarely. Thus, Mzr1-induced genes might interfere with pathogenic development.

Overexpression of *biz1* induces expression of *mig1*, *mig2-5*, and *mig2-6*. In addition, it has been found that Biz1 is required for downregulation of the mitotic cyclin *clb1* (Flor-Parra *et al.*, 2006). Clb1 forms a complex with Cdk1 and, together with the Clb2-Cdk1 complex, is required for the G2/M transition in *U. maydis* (Garcia-Muse *et al.*, 2004). Therefore, overexpression of *biz1* arrests the cell cycle and confers elongated and polar growth phenotype. Furthermore, it has been confirmed that *biz1* is expressed at all stages during pathogenic development and required for pathogenic development of *U. maydis* beyond penetration. In particular, the *biz1* deletion mutant cells show a severe reduction in appressoria formation and plant penetration. Those hyphae that invade the plant arrest their pathogenic development after plant penetration (Flor-Parra *et al.*, 2006).

These results showed that overexpression of both *biz1* and *mzr1* confer an elongated growth phenotype, therefore it would be interesting to address whether Mzr1 is involved in the control of *clb1* expression and thus plays a role in the cell cycle too.

3.7 Outlook

Based on the finding that Mzr1 needs Biz1 for *mig2-5* regulation, it would be interesting to identify the possible Mzr1-Biz1 interaction. Presently we are trying to verify the interaction between Mzr1 and Biz1 proteins using the yeast-two

hybrid system. This result may offer further insight into the regulation model for *mig2-5* and more clues to investigate the protein-protein interactions involving zinc fingers. In addition, it would also be an exciting effort to investigate the *mig2-5* regulation by the Mzr1-Biz1 complex, which can contribute more information about the biological roles for zinc finger protein-protein interactions.

Up to now, 11 *znf* gene deletion mutants have been constructed, and none of them could show obvious influence for expression of *mig2-1* and *mig2-2* (see **Fig. 7**). However, functions of many zinc finger proteins in *U. maydis* are still unknown (see **Table 1**). Further investigation for the remaining *znf* genes may uncover additional regulators required for *mig2-1* and *mig2-2*.

In addition, to prove the regulation model described above (see **Fig. 34**), it is necessary to investigate the protein-DNA binding and the binding sites between Biz1, Znf23 and the *mig2-5* promoter.

4 Materials and methods

4.1 Materials and their sources of supply

4.1.1 Chemicals, Buffer, Enzymes and Kits

All chemicals used for my experiments were ordered from Fluka, Invitrogen, Roth or Sigma.

Restriction enzymes, the ligase and the Phusion DNA Polymerase were obtained from New England Biolabs (NEB). Taq-Polymerase was obtained from Fermentas. The Klenow enzyme was ordered from Roche. The Anti-His antibody was obtained from Invitrogen. The Anti-Mouse IgG was obtained from Promega. The complete protease inhibitor cocktail was ordered from Roche. Poly [dI-dC] was obtained from Sigma. The Trizol reagent was ordered from Invitrogen. The Novozyme was obtained from other group (Kämper lab). The antarctic phosphatase was ordered from NEB. The protein marker peqGold protein-marker IV was ordered from peQlab. The RNase, DTT, DNaseI and were ordered from Invitrogen. Specific buffers used for each experiment are listed within the corresponding method.

The concentrations of antibiotics used for normal plates in this work were described as follows:

PD/Cbx: 2 µg/ml of carboxin

PD/Nat: 150 µg/ml of nourseothricin

PD/Hyg: 200 µg/ml of hygromycin

The following kits were used following the protocol recommended by the supplier:

-TA Cloning Kit (Invitrogen) for directly cloning of PCR products

-Jet Sorb Gel Extraction Kit (GENOMED) for DNA extraction from gels

- QIAquick Gel Extraction Kit (QIAGEN) for DNA extraction from gels
- QIAquick PCR Purification Kit (QIAGEN) for PCR product and plasmid DNA purification
- Ni-NTA Spin Kit (QIAGEN) for His-tag fusion protein purification
- Western Blotting Detection Kit (GE Healthcare)

4.1.4 Plasmids constructed in this work

Vectors for the deletion of specific genes

For the construction of gene deletion vectors, PCR was performed to amplify an approximately 1 kb DNA fragment upstream of the respective ORF using the primer pairs given in **Table 7** and the genomic DNA of *U. maydis* strain 521 as template. Additionally, another approximately 1 kb DNA fragment downstream of the respective ORF was amplified using another primer pair (**Table 7**). The two PCR products were digested with SfiI and then ligated with the hyg-SfiI fragment, which was isolated from plasmid pBShnn (Kämper, 2004) by SfiI digestion. Subsequently, the ligation product was ligated into the pCR4.0 TOPO plasmid vector. For generation of gene deletions, the resulting vector was used as template to amplify an approximately 4 kb DNA fragment (upstream fragment + hyg-SfiI fragment + downstream fragment) using Taq-Polymerase. This PCR product was transformed into strain JF1 to generate *U. maydis* deletion mutants by homologous recombination.

Table 7. plasmid for gene deletion and primers used for their construction.

Plasmids	Primers*	Comments
pmyb1	M1-1/M1-2; M1-3/M1-4	For the <i>myb1</i> deletion
pmyb2	M2-1/M2-2; M2-3/M2-4	For the <i>myb2</i> deletion
pmyb3	M3-1/M3-2; M3-3/M3-4	For the <i>myb3</i> deletion
pmyb8	M8-1/M8-2; M8-3/M8-4	For the <i>myb8</i> deletion
pz3	JF209/JF210; JF211/JF212	For the <i>znf3</i> deletion
pz4	JF213/JF214; JF215/JF216	For the <i>znf4</i> deletion
pz5	Z5-1/Z5-2; Z5-3/Z5-4	For the <i>znf5</i> deletion
pz7	Z7-1/Z7-2; Z7-3/Z7-4	For the <i>znf7</i> deletion
pz9	Z9-1/Z9-2; Z9-3/Z9-4	For the <i>znf9</i> deletion
pz12	Z12-1/Z12-2; Z12-3/Z12-4	For the <i>znf12</i> deletion
pz14	Z14-1/Z14-2; Z14-3/Z14-4	For the <i>znf14</i> deletion
pz20	Z20-1/Z20-2; Z20-3/Z20-4	For the <i>znf20</i> deletion
pz21	Z21-1/Z21-2; Z21-3/Z21-4	For the <i>znf21</i> deletion
pz22	Z22-1/Z22-2; Z22-3/Z22-4	For the <i>znf22</i> deletion
pz23	Z23-1/Z23-2; Z23-3/Z23-4	For the <i>znf23</i> deletion
pz25	Z25-1/Z25-2; Z25-3/Z25-4	For the <i>znf25</i> deletion

* See Table 8 for sequence and details.

potef-Z22-cbx

The *otef* promoter was amplified by PCR using the primer pair YZ17/YZ18, Taq-Polymerase and the plasmid pHD3 as template. The PCR product was cleaved with NdeI/EcoRV and then inserted into the pCZ22v plasmid vector, in which the *crg1* promoter has been removed with NdeI and PmlI. The resulting plasmid was linearized with SpeI and then filled up with the Klenow enzyme. For the *cbx* cassette preparation, the plasmid pSL-cbx was cleaved with NotI and then filled up with Klenow enzyme. Finally, the blunt *cbx* fragment was inserted into the SpeI linearized plasmid vector to generate *potef-Z22-cbx*. This plasmid was confirmed by restriction enzyme control digestion and used for transformation of the *U. maydis* strain SG200 to generate the strains SG200/*potef-mzr1* and SG200 Δ *biz1*/*potef-mzr1*.

potef-Z22-nat

The *otef* promoter was amplified by PCR using the primer pair YZ17/YZ18, the Phusion DNA Polymerase and the plasmid pHD3 as template. The PCR product was cleaved with NdeI/EcoRV and then inserted into the pCZ22v plasmid vector, in which the *crg1* promoter has been removed with NdeI and PmlI. The resulting plasmid was linearized with NotI and was then dephosphorylated. The plasmid pSL-nat was cleaved with NotI to isolate the *nat*-resistance cassette. Finally the *nat*-resistance cassette was inserted into the NotI linearized plasmid vector described above to generate *potef-Z22-nat*. This plasmid was confirmed by restriction enzyme control digestion and used for *U. maydis* transformation to generate the strains JF1/*potef-mzr1* and JF1 Δ *mzr1*/*potef-mzr1*.

pTOPO-Z22

The 1098 bp *mzr1* ORF was amplified by PCR using the primer pair TOPO1/TOPO2n, the Phusion DNA Polymerase and cDNA from JF1/*crg1-mzr1* as PCR template (prepared above, see **Fig.7** and 4.2.8 below). A 1102 bp PCR product was ligated with the pBAD102/D-TOPO vector. This plasmid vector

contains coding sequences for a C-terminal His-tag and an N-terminal thioredoxin for increased translation efficiency and solubility of heterologous proteins. The His-tag fusion was used for the detection of protein expression and for the purification of the recombinant fusion protein. The *araBAD* promoter regulates gene expression in this plasmid. The resulting plasmid pTOPO-Z22 was confirmed by restriction enzyme control digestion and used for *E. coli* transformation to express the truncated Mzr1 fusion protein in *E. coli*.

pmig-200/M

A 200-bp 5'-CCA-3' mutant *mig2-5* promoter fragment was amplified by PCR using the primer pair YZ73/YZ74, the Phusion DNA Polymerase and the plasmid pJS12 (Farfsing *et al.*, 2005) as template. The PCR product was inserted into the pCR4.0 TOPO plasmid vector. The resulting plasmid pmig-200/M was confirmed by restriction enzyme control digestion and used to isolate a 200-bp 5'-CCA-3' mutant *mig2-5* promoter fragment by digestion with BamHI.

pmig-120/M

A 120-bp 5'-CCA-3' mutant *mig2-5* promoter fragment was amplified by PCR using the primer pair YZ77/YZ78, the Phusion DNA Polymerase and the plasmid pJS12 (Farfsing *et al.*, 2005) as template. The PCR product was inserted into the pCR4.0 TOPO plasmid vector. The generated plasmid pmig-120/M was confirmed by restriction enzyme control digestion and used to isolate a 120-bp 5'-CCA-3' mutant *mig2-5* promoter fragment by digestion with BamHI.

p160-C

A 160-bp *mig2-5* promoter fragment was amplified by PCR using the primer pair YZ75/YZ76, the Phusion DNA Polymerase and the genomic DNA of *U. maydis* strain 521 as template. The PCR product was inserted into the pCR4.0 TOPO plasmid vector. The resulting plasmid p160-C was used to isolate a 160-bp *mig2-5* promoter by digestion with BamHI, which served as negative control in EMSA.

4.1.5 *Escherichia coli* strain

Escherichia coli K12 strain TOP10 (Invitrogen) was used as host strain for plasmid amplifications. This strain allows stable replication of high-copy number plasmids.

4.1.6 PCR primers used in this work

All primers used in this work were ordered from MWG BIOTECH.

4.2 Genetic, microbiological and cell biological methods

4.2.1 Plasmid preparation from *E. coli*

The *E. coli* strain carrying the desired plasmid was grown in liquid dYT or LB medium (the concentration of Ampicillin used as selection marker was 100µg/ml) overnight under shaking at 37°C. Cells were harvested by centrifugation (30 sec, 13000 rpm), and the cell pellet was resuspended in 350 µl STET solution. 25 µl lysozyme solution was added. After mixing, the suspension was incubated at RT for 30 sec and then heated at 95°C for 50 sec. After centrifugation (10 min, 13000 rpm), the bacterial debris was removed using a toothpick. Then, 37 µl of Mini III solution and 420 µl of iospropanol were added. After mixing, the suspension was incubated at RT for 5 min. The supernatant was removed after centrifugation (5 min, 13000 rpm). The pellet was washed with 900 µl of 70% ethanol. Subsequently, the supernatant was removed as complete as possible after centrifugation (3 min, 13000 rpm). The pellet was dried at RT for 5 min. Finally, the DNA pellet was resuspended in 80 µl TE solution containing 20 µg/ml RNase.

in H₂O

4.2.2 Transformation of *U. maydis*

U. maydis cells were grown overnight in YEPS_{light} medium at 28°C until an OD₆₀₀ of 0.3–0.8 was reached. Cells were harvested by centrifugation (10 min, 13000 rpm). The cell pellet was washed with 20 ml SCS medium and was then resuspended in 4 ml SCS medium containing 5 mg/ml Novozyme. The sample was incubated at RT for 10 min at RT to digest the cell wall material (examined under the microscope). After rounding up of the elongated *U. maydis* cells, SCS solution was added to a volume of 40 ml. The sample was gently resuspended. After centrifugation (10 min, 2000 rpm), the cell pellet was washed two-times with 20 ml SCS buffer (8 min, 2000 rpm). Then, it was washed for an additional time with 20 ml STC buffer. Finally, the cell pellet was resuspended in 1 ml STC. The protoplasts were stored in aliquots at -80°C. 1-5 µg linearized DNA and 1 µl heparin solution were mixed and incubated on ice for 10 min. Then, 50 µl protoplasts were added and gently mixed. The mixture was incubated on ice for 10 min. After addition of 600 µl STC/PEG, the mixture was incubated on ice for further 15 min. The suspension was plated on a regeneration-agar plate and was then incubated at 28°C for ca. 5 days until colonies appeared.

SCS

20 mM Na-citrate, pH5.

1) Top agar
1.5% (w/v) Bacto Agar
1 M Sorbitol
in YEPS medium
2) Bottom agar
Top agar plus double concentrated antibiotic

4.2.3 Preparation of Glycerol cultures

For long time-storage of *U. maydis* strains, the cells were frozen at -80°C (glycerol cultures). *U. maydis* cells were grown in YEPS_{light} medium at 28°C overnight under shaking until an OD₆₀₀ of 1 was reached. 1 ml of cell culture was mixed with 1 ml NSY Glycerol solution. Mixture was incubated at RT for 20 min and then stored frozen at -80°C .

NSY Glyceol

8 g Bacto nutrient broth
1 g Yeast extract
5 g Sucrose
800 ml 87% glycerol
fill up to 1l with H₂O

4.2.4 Genomic DNA isolation of *U. maydis*

U. maydis cells were grown in YEPS_{light} medium at 28°C overnight under shaking. Cells from 2 ml of cell culture were harvested by centrifugation (2 min, 13000 rpm). The supernatant was removed. 0.3 g glass beads (acid-washed), 400 μl lysis buffer (see below) and 500 μl phenol/chloroform (1:1, v/v) were added. The sample was placed on a Vibrax-VXR shaker (IKA) running at $3/4$ speed for ~ 8 min. About 400 μl of the upper phase were collected in a 1.5 ml Eppendorf tube after centrifugation (15 min, 13000 rpm). Then, the 2.5-fold volume of 100% ethanol was added. The sample was mixed and incubated at RT for 5 min. The supernatant was removed after centrifugation (5 min, 13000 rpm). The pellet was washed with 1 ml 70% (v/v) ethanol. The residual liquid in the tube was removed as complete as possible after centrifugation (3 min, 13000 rpm). Finally, the dry DNA pellet was resuspended in 50 μl TE solution containing 20 $\mu\text{g}/\text{ml}$ RNase.

Lysis buffer

2% (w/v) Triton
1% (w/v) SDS
1 mM EDTA
100 mM NaCl
10 mM Tris-Cl, pH 8.0
in ddH₂O

4.2.5 Induction of inducible promoters

The use of the arabinose inducible *crgI* promoter allows the controlled regulation of gene expression by a change of the cultivation medium. The *crgI* promoter controlled genes are repressed in CM-glucose medium where glucose is the sole carbon source. Inducible conditions are given when arabinose is the sole carbon source in CM-arabinose medium. To induce the expression of *crgI* promoter controlled genes, *U. maydis* strains were grown in CM/Glu at 28°C for 12 hours. Cells were harvested by centrifugation (10 min, 3000 rpm) and were then washed two-times with ddH₂O. Cell pellets were resuspended in CM/Ara medium. Finally, cultures were incubated at 28°C for 15 hours (until an OD₆₀₀ of 0.8 was reached) under shaking, with a starting OD₆₀₀ of 0.1.

4.2.6 RNA isolation from *U. maydis*

U. maydis cells were grown in 15 ml CM medium (1% glucose or arabinose) at 28°C overnight under shaking until an OD₆₀₀ of 0.5-0.8 was reached. Cells were harvested by centrifugation (10 min, 13000 rpm). The supernatant was discarded and the cells were resuspended in the remaining medium. The suspension was transferred to a 1.5 ml Eppendorf tube. The supernatant was removed after centrifugation (3 min, 13000 rpm). Cells were frozen in liquid nitrogen. Next, 440 µl aqua phenol, 400 µl AE buffer and 40 µl 10% (w/v) SDS were added into the tube. The sample was mixed for 20 sec and then incubated at 65°C for 4 min

under shaking (13000 rpm). Next, the sample was frozen at -80°C for 7 min until phenol crystals were formed. This mixture was thawed at RT for maximum 5 min. The upper phase was collected in a new 1.5 ml Eppendorf tube after centrifugation (10 min, 15000 rpm at 4°C). The 1-fold volume of aqua phenol/chloroform (1:1, v/v) was added. The upper phase was collected in a 1.5 ml Eppendorf tube after centrifugation (5 min, 13000 rpm at 4°C). The 0.1-fold volume of Mini III and 2.5-fold volume of 100% ethanol were added into the tube. The sample was mixed by reversion and then incubated at -20°C for 1 hour. The supernatant was removed after centrifugation (20 min, 20000 rpm at 4°C). The pellet was washed with 1 ml 80% (v/v) ethanol. The supernatant was removed after centrifugation (10 min, 20000 rpm at 4°C). Finally, the RNA pellet was dissolved in 30 μl RNase free H_2O .

AE buffer

50 mM NaAc, pH 5.3
10 mM Na_2EDTA

Salt solution (Holliday, 1974)

16 g KH_2PO_4
4 g Na_2SO_4
8 g KCl
4 g $\text{MgSO}_4 \times 7 \text{H}_2\text{O}$
1.32 g $\text{CaCl}_2 \times 2 \text{H}_2\text{O}$
8 ml trace elements solution
in 1l H_2O , filter sterilized

Trace elements solution

60 mg H_3BO_3
140 mg $\text{MnCl}_2 \times 4\text{H}_2\text{O}$
400 mg ZnCl_2
40 mg $\text{NaNO}_3 \times 2\text{H}_2\text{O}$
100 mg $\text{FeCl}_3 \times 6\text{H}_2\text{O}$
40 mg $\text{CuSO}_4 \times 5\text{H}_2\text{O}$
in 1l H_2O , filter sterilized

CM (without glucose)

1.5 g NH_4NO_3
2.5 g casamino Acids
0.5 g DNA degree free acid
1 g Yeast extract
10 ml vitamin solution
62.5 ml salt solution
filled up to 1l with H_2O
pH 7.0

Vitamin solution

100 mg Thiamine
50 mg Riboflavin
50 mg Pyridoxine
200 mg Calcium pantothenate
500 mg p-Amino benzo acid
200 mg Nicotinic acid
200 mg Choline chloride
1 g myo-inositol
in 1l H_2O , filter sterilized

4.2.7 Total RNA isolation from plant tissue

1 g plant tissue was ground in liquid nitrogen. The resulting powder was transferred to a 15 ml falcon tube containing 10 ml TRIZOL. The sample was mixed by vortexing until no clumps remained in the tube. The mixture was incubated at RT for 15 min. Next, 2 ml chloroform was added to the tube. After mixing by vortexing (10 sec), the mixture was incubated at RT for 3 min. The upper aqueous phase was collected in a new falcon tube after centrifugation (15 min, 3500 rpm at 4°C). The sample was mixed with 1-fold volume of phenol/chloroform (1:1, v/v, and equilibrated with TE to pH 8) for 10 seconds by vortexing. The aqueous upper phase was collected after centrifugation (10 min, 3500 rpm at 4°C). 5 ml isopropanol were added, and the sample was mixed by inversion. The mixture was incubated on ice for 10 min. The supernatant was removed after centrifugation (15 min, 9000 rpm at 4°C). Finally, the dry RNA pellet was dissolved in 80 µl RNase free H₂O on ice. The sample was stored at -20°C or -80°C (for long time-storage).

4.2.8 Dnase treatment of RNA and reverse transcription

Following components were added in a 1.5 ml Eppendorf tube:

1. Dnase treatment:

1-15 µg total RNA

5 µl 10x DP buffer

1.5 µl 100 mM DTT (added before the RNase inhibitor)

0.3 µl human placental RNase inhibitor (40 u/µl; Roche)

2 µl DNaseI (RNase free; 10u/µl; Roche)

H₂O up to 50 µl

The mixture was incubated at 37°C for 30 min, and then 200 µl of TE buffer were added. The sample was extracted two times with the same volume of phenol/chloroform (vortexed and centrifuged at 15000 rpm, 4°C for 5 min). The upper phase was collected in a new Eppendorf tube. The 0.1-fold volume of

MiniIII and 3-fold volume of 100% ethanol were added into the tube. The mixture was incubated at -20°C for 15 min. After centrifugation (10 min, 22000 rpm at 4°C), the pellet was washed with 1 ml 70% (v/v) ethanol (10 min, 22000 rpm at 4°C). After removing of the supernatant, the pellet was dissolved in 20 µl ddH₂O. 0.5-2 µg of RNA were transferred into a 1.5 ml Eppendorf tube for subsequent reverse transcription.

2. Reverse transcription:

0.5-2 µg RNA (see above)

1.5 µl oligo dT primer CBAP5 (10 µM; 5'TTGTACAAGCT₃₀VN)

1 µl 10 mM dNTPs

H₂O to 12.5 µl

The mixture was incubated at 65°C for 5 min and was then transferred on ice for 2 min (to remove the secondary structures and anneal the primer). The following components were added:

4 µl 5x 1st Strand buffer (Gibco)

2 µl 100 mM DTT

0.5 µl Roche Rnase inhibitor (40 u/µl)

1 µl SuperScript III RT (200 u/µl, Gibco)

The mixture was incubated at 40°C for 5 min, and was then incubated at 42°C (up to 55°C) for 55 min. Finally, the sample was heated at 90°C for 5 min and was stored at -20°C.

10x DP buffer

100 mM Tris-HCl, pH 8.3

500 mM KCl

15 mM MgCl₂

in H₂O

4.2.9 Southern hybridization

A DNA sample was digested with appropriate restriction enzyme(s) and then was loaded onto a 1% (w/v) TBE agarose gel (10x12 cm). The gel was run at 110 V for 2 hours. Next, the gel was incubated in 0.25 M HCl solution for 15 min, and then in denaturation buffer for 25 min under gentle shaking. Finally, the gel was incubated in renaturation buffer for 15 min under gentle shaking. DNA was transferred to a Hybond-N+ membrane (Amersham Biosciences) in 20-fold SSC buffer overnight (**Fig. 36**). Then, the membrane was dried and stored at 4°C.

Figure 36. DNA transfer to hybond membrane.

DNA was transferred to a Hybond-N+ membrane in 20-fold SSC buffer overnight.

After blotting, the membrane prepared above was dried and UV cross-linked (Stratalinker, STRATA GENE), followed by incubation in Southern hybridization buffer at 65°C for 30 min under rotation. The Southern hybridization buffer was discarded and the radioactively labeled probe (see 'Probe labeling') was added. The membrane was incubated in the probe solution at 65°C overnight under rotation. After 12-24 h, the membrane was washed with S1 buffer for a short period (15-30 min). Then, the membrane was incubated in S2 and S3 buffer at 65°C for 30 min under rotation. Finally, the membrane was dried and exposed within a screen cassette for at least one day, followed by laser scanning (STORM Phosphorimager).

5x TBE	Denaturation buffer
440 mM Tris-Base	1.5 M NaCl
440 mM Boric acid	0.4 M NaOH
10 mM EDTA, pH 8.0	in H ₂ O
in H ₂ O	
Renaturation buffer	20x SSC
1.5 M NaCl	3 M NaCl
282 mM Tris-HCl	0.3 M Natriumcitrat
218 mM Tris-Base	in H ₂ O
in H ₂ O	pH 7.0

4.2.10 Northern hybridization

5-15 µg RNA sample was transferred into a 1.5 ml Eppendorf tube on ice. The following components were added into the tube:

2.4 µl 10x MOPS
 2.4 µl 8M Glyoxal
 12 µl DMSO
 dd H₂O up to 24 µl

The mixture was incubated at 50°C for 1 hour, and was then transferred on ice.

6 µl RNA loading buffer were mixed with the RNA sample. A 1% (w/v) agarose gel (in 1-fold MOPS buffer) was prerun at 85V for 5-10 min, and then the RNA mixture was loaded. The gel was run at 85V for 2 hours in 1-fold MOPS buffer. The orientation of the gel in the chamber and the polarity of the chamber were inverted every 30 minutes to keep the pH value. Afterwards, the gel was equilibrated in 20-fold SSC buffer for 10-15 min under gentle rotation. The RNA sample in the gel was transferred to a Hybond-NX membrane (Amersham Biosciences) in 20-fold SSC buffer overnight (see **Fig. 36**). The dry membrane was UV cross-linked (Stratalinker, STRATA GENE). The membrane was stained in methylene blue solution for 5 min under gentle shaking. Next, the membrane was rinsed in ddH₂O for 10 min under gentle rotation. Finally, the dry membrane

was stored at 4°C.

Next, the membrane prepared above was incubated in Northern hybridization buffer at 60°C for 30 min under rotation. The Northern hybridization buffer was discarded and the radioactively labeled probe (see 'Probe labeling') was added. The membrane was incubated in the probe solution at 60°C overnight under rotation. After 12-24 h, the membrane was washed with Northern wash buffer by shaking. Then, the membrane was incubated in Northern wash buffer at 60°C for 30 min under rotation. Finally, the membrane was dried and exposed to a cassette for at least one day, and then the cassette was scanned (STORM Phosphorimager).

10x MOPS

200 mM MOPS
80 mM Natriumacetate
10 mM Na₂-EDTA
in H₂O, pH 7.0

Gel loading buffer (for 10 ml)

1 ml 10x MOPS
5 g Glycerin
50 mg Bromphenol blue
50 mg Xylene blue
add H₂O to 10 ml

Methylene blue solution

300 mM Natriumacetate
0.02 (w/v) methylene blue
in H₂O

4.2.11 Isolation of the Mzr1 fusion protein from *E. coli*

E. coli strains carrying the plasmid pTOPO-Z22 were grown in 100 ml LB medium containing 100 µg/ml Amp at 37°C under shaking to an OD₆₀₀ of 0.5. Arabinose stock solution was added to a final concentration of 0.0002% (w/v), and then the incubation was continued for 4 hours under shaking. Cells were harvested by centrifugation (3 min, 10000 rpm). The cell pellet was kept frozen at -80°C. Next, the cell pellet was thawed and resuspended in 3.5 ml lysis buffer. The sample was again frozen in liquid nitrogen. Next, the cell sample was thawed and lysed two-times at 10000-11000 psi using a French-Press (Minicell). The supernatant was collected after centrifugation (20 min, 10000 rpm at 4°C). Six

Ni-NTA spin columns (QIAGEN) were equilibrated with 600 μ l lysis buffer each by centrifugation (2 min, 2000 rpm). 550 μ l of supernatant prepared above were loaded on each column. After centrifugation (2000 rpm for 3 min), each column was washed three-times with 600 μ l wash buffer (2000 rpm for 2 min). Next, each column was eluted twice with 230 μ l elution buffer. The eluates were collected in 1.5 ml Eppendorf tubes. A PD-10 column was equilibrated with 5x5 ml protein buffer and then 2.5 ml of the protein eluate were loaded. PD-10 column was then eluted with 3.5 ml protein buffer and the eluate was collected. The prepared protein sample was stored frozen in aliquots at -80°C .

 in H_2O

4.2.12 Protein isolation from *U. maydis*

U. maydis cells were grown in 100 ml CM medium (containing 1% arabinose if gene expression was under the *crg1* promoter) at 28°C overnight under shaking. Cells were harvested by centrifugation (10 min, 3500rpm) and were then resuspended in 2.5 ml protein buffer. Sample was frozen in liquid nitrogen. Next, the cell sample was thawed and lysed two-times using a French-Press (Minicell). The supernatant was collected after centrifugation (20 min, 1000rpm at 4°C). The resulting protein sample was stored frozen in aliquots at -80°C .

Protein buffer

25 mM HEPES, pH 7.9
50 mM KCl
2.5 mM DTT
1-fold complete protease inhibitor cocktail
in H₂O

4.2.13 Preparation of DNA fragments

The 723 bp *eGFP* fragment used for Northern blot analysis was isolated from plasmid p123 by NcoI/NotI digestion (Basse *et al.*, 2000). Gene-specific probes for *mig2-1*, *mig2-2*, *mig2-5* have been described (Basse *et al.*, 2002) and were isolated as EcoRI fragments from pCR2.1-TOPO. The gene-specific probe for *mig1* has been described (Basse *et al.*, 2000) and was isolated as EcoRI fragment from pCR2.1-TOPO. A *mzr1* ORF specific fragment was isolated from pZ22 by digestion with PstI/XbaI; a *biz1* ORF specific fragment was prepared from pZ8 by digestion with MfeI/NcoI; a *znf7* ORF specific fragment was isolated from pZ7 by digestion with XbaI/NcoI; a *znf12* ORF specific fragment was isolated from pZ12 by digestion with MluI; a *znf23* ORF specific fragment was isolated from pZ23 by digestion with HindIII/NcoI. A *mig2-6* ORF specific fragment has been described (Farfsing *et al.*, 2005) and was isolated as EcoRI fragment. A 500-bp *mig2-5* promoter fragment was prepared from pJM17 (Farfsing *et al.*, 2005) by digestion with XbaI/BamHI. A 200-bp *mig2-5* promoter fragment (from -320 to -120) was isolated from plasmid pJM19 (Farfsing *et al.*, 2005) by digestion with XbaI/BamHI. The 120-bp *mig2-5* promoter fragment (from -240 to -120) was isolated from plasmid pJM20 (Farfsing *et al.*, 2005) by digestion with XbaI/BamHI. The 200-bp CCA mutant *mig2-5* promoter fragment was isolated from pmig-200/M by BamHI digestion. A 120-bp CCA mutant *mig2-5* promoter fragment was isolated from pmig-120/M by BamHI digestion. The 160-bp *mig2-5* promoter fragment (from -161 to -1) used as control in EMSA was prepared from p170-C by BamHI digestion. Furthermore, the 200-bp *mig2-5* promoter fragment used as binding competitor was amplified by PCR using the primer pair

YZ70/YZ71, the Phusion DNA Polymerase and pJM19 as template; the 200-bp CCA mutant *mig2-5* promoter fragment used as binding competitor was amplified by PCR using the primer pair YZ70/YZ71, the Phusion DNA Polymerase and pJS12 as template; the 120-bp *mig2-5* promoter fragment used as binding competitor was amplified by PCR using the primer pair YZ71/YZ72, the Phusion DNA Polymerase and pJM19 as template; the 120-bp CCA mutant *mig2-5* promoter fragment used as binding competitor was amplified by PCR using the primer pair YZ71/YZ72, the Phusion DNA Polymerase and pJS12 as template. The isolated DNA fragments described were either used for Northern blot analysis (see probe labeling, 4.2.16) or for the electrophoretic mobility shift analysis (see EMSA, 4.2.15).

4.2.14 Western blot

An appropriate protein sample was mixed with the loading buffer in an Eppendorf tube. The mixture was heated at 95°C for 5 min, and then was immediately transferred on ice. Next, the protein mixture was loaded onto a 12% (v/v) SDS-polyacrylamide gel (8x9 cm, BIO-RAD). The gel was run at 80 volt for 30 min in running buffer, then at 100 volt for 1 hour. Six sheets of thick Whatman and one sheet of Hybond-P membrane (Amersham Biosciences) were prepared at the appropriate size (6x9 cm). The Whatman papers and the Hybond-P membrane, together with the gel, were arranged in the following order:

- a. two sheets of Whatman paper
soaked with Anode I buffer
- b. one sheet of Whatman paper
soaked with Anode II buffer
- c. Hybond-P membrane
 - 1) soaked with methanol for 1 min
 - 2) rinsed with ddH₂O
 - 3) soaked with Anode II buffer for no more than 10 min
- d. SDS gel

- rinsed with ddH₂O
 e. three sheets of Whatman paper
 soaked with Cathode buffer

The membrane was blotted at 0.8 mA/cm² for 1 hour. Next, the membrane was soaked at 4°C overnight (or at RT for 1 hour) in blocking buffer under gentle shaking, and was then soaked at RT for 15 min in fresh blocking buffer under gentle shaking. The antibody against the protein tag of interest was added in blocking buffer at an appropriate dilution. After one hour gentle shaking at RT, the membrane was washed three-times with blocking buffer (10 min for each wash under gentle shaking). The second IgG antibody was diluted in blocking buffer according to the recommendation of the supplier and added to the membrane. The reaction was incubated at RT for 30 min under gentle shaking. Next, the membrane was washed twice with PBS/0.1% (w/v) Tween solution (5 min for each wash under gentle shaking) and once with PBS buffer for 5 min. After removing of excess liquid, the membrane was soaked in detection mixture (Amersham ECL Plus Western Blotting Detection System, GE) for 5 min. Finally, the membrane was exposed to an X-ray film (medical X-Ray screen film, CEA) for 2 min and the film was developed.

12% SDS gel (for 2 gels)

1) lower gel	2) upper gel
5 ml H ₂ O	4.3 ml H ₂ O
3.75 ml 4x stacking gel buffer	1.875 ml 4x running gel buffer
150 µl 10% SDS	75 µl 10% SDS
6 ml Acrylamid (Acrylamid 30%, Mix 37.5:1, AppliChem)	1.2 ml Acrylamid (Acrylamid 30%, Mix 37.5:1, AppliChem)
75 µl 10% APS	37.5 µl 10% APS
7.5 µl Temed	3.75 µl Temed

4x stacking gel buffer

15.39% (w/v) Tris-Base
 3.69% (w/v) Tris-HCl
 in H₂O, pH 8.8

4x running gel buffer

0.67% (w/v) Tris-Base
 7.02% (w/v) Tris-HCl
 in H₂O, pH 6.8

10x Running buffer

1.92 M Glycin
 0.25 M Tris-Base
 1% (w/v) SDS
 in H₂O

1x PBS
 0.1% (w/v) Tween 20
 5% (w/v) low fat powder
 milk
 in H₂O

2x loading buffer

130 mM Tris-Cl, pH8.0
 20% (v/v) Glycerol
 4.6% (w/v) SDS
 0.02% Bromophenol blue
 2% DTT

10x PBS

80 g NaCl
 2 g KCl
 14.4 g Na₂HPO₄
 2.4 g KH₂PO₄
 in H₂O, pH 7.2

Cathode buffer

25 Mm Tris-Base
 40 mM 6-amino.hexanoic acid
 in H₂O, pH 9.4

Anode I buffer

0.3 M Tris-Base
 in H₂O, pH 10.4

Anode II buffer

25 mM Tris-Base
 in H₂O, pH 10.4

4.2.15 EMSA

A 4% acrylamide gel (20x20 cm, ~50 ml, BIO-RAD) was prerun at 12 mA for 1.5 h. The protein sample, 1 µg poly [dI-dC] (to inhibit unspecific binding, Sigma), 1-fold binding buffer, 10% (w/v) glycerol and a suitable volume of pure water for a total volume of 20 µl after the addition of DNA probe were mixed in a 1.5 ml Eppendorf tube. The mixture was incubated at RT for 15 min, and then an excess of cold DNA competitor was added if a binding competition assay was performed. In this case, a preincubation of 20 min was done. Then, 6 µg of the ³³P radioactively end-labeled DNA probe was added. The reaction was incubated at RT for additional 35 min. The mixture was loaded onto the gel, which then was run at 12 mA for 3.5 h. The gel was transferred to a Whatman paper and was dried at 85°C vacuum for 45 min. The vacuum was maintained for additional 15 min after heating was stopped. Finally, the gel was exposed within a screen cassette for 2 days and subsequently scanned (STORM Phosphorimager).

4% acrylamide gel	5-fold binding buffer
0.5-fold TBE buffer	100 mM HEPES, pH 7.9
4% acrylamide mix (37.5:1 acrylamide: bisacrylamide)	250 mM KCl
1% (w/v) glycerol	10 mM MgCl ₂
0.07% APS (using freshly prepared 10% APS stock solution)	1 mM ZnCl ₂
35 µl TEMED (for 50 ml gel preparation) in H ₂ O	0.5 mM EDTA
	5 mM DTT
	1.5 mg/ml BSA in H ₂ O

4.2.16 Probe labeling

50 ng of DNA fragment to be labeled were mixed with ddH₂O (total volume was 33 µl) and heated at 95°C for 5 min, and then the DNA sample was transferred on ice. After 2 min of incubation, 5 µl 10-fold labeling buffer (NEB) and 6 µl of 1 mM dNTPs (without dCTP, final concentration for dATP, dGTP and dTTP was 0.12 mM) were added. Next, 1 µl Klenow enzyme (NEB) and 50 µCi (5 µl) ³²P-labeled dCTP (HARTMANN ANALYTIC) were added. The reaction was incubated at 37°C for one hour and was then loaded on a MicroSpin S-300 HR column (centrifuged for 1 min at 2700 rpm before use, GE Healthcare). After centrifugation (2 min, 2700 rpm), the eluate was mixed with 13 ml hybridization buffer (Northern or Southern buffer) and then was heated at 97°C for 10 min. The labeled probe was used for Northern or Southern blot analysis (also could be stored at 4°C for a short period).

4.2.17 Cell density determination of *U. maydis*

U. maydis cell density in culture was determined by measuring the optical density with a Novosec II Photometer (Pharmacia Biotech) at a wavelength of 600 nm. The cell culture had to be diluted to a value below OD₆₀₀ 0.8 before determination to ensure a linear range. A value of OD₆₀₀ 1 correlates to 1-2x 10⁷ cells/ml.

4.2.18 Concentration determination of DNA, RNA and protein

The concentrations of DNA, RNA and protein samples were determined using a ND-1000 spectrophotometer (NanoDrop Technologies, Inc.).

4.2.19 Chlorazole Black E staining

This method is modified from (Brachmann *et al.*, 2003). Infected plant tissue was harvested and placed into 2 ml Eppendorf tubes containing 100% ethanol. This tube was then incubated at RT overnight until the chlorophyll was completely removed. The plant tissue was washed with H₂O, then soaked in 10% (w/v) KOH solution and heated at 90°C for 3 hours. Next, it was washed with H₂O after removal of KOH solution. Finally, the plant tissue was soaked in chlorazole solution for 1-2 days and was stored in 50% (w/v) glycerin.

Chlorazole solution

¹/₃ 100% glycerin

¹/₃ lactic acid

¹/₃ 0.03% (w/v) chlorazole black E solution

4.2.20 Plant infection

U. maydis overnight cultures in YEPS_L medium were adjusted in H₂O to an OD₆₀₀ of 2.0. Cell suspensions were injected into the basal stem of six-day-old corn seedlings (Early Golden Bantam; Olds Seeds, Madison, WI) using a syringe and gauge needles (BD Drogheda).

4.2.21 Light Microscopy observation

Infected leaf tissue was excised from regions adjacent to chlorotic areas or from tumor tissue with a razor blade (Basse *et al.*, 2000). Cells in culture or plant tissue

were observed with differential interference contrast optics (DIC) or under fluorescence microscopy using a Zeiss Axioplan II microscope (Zeiss, Jena, Germany). All microscopical observations were done with a CoolSNAP-HQ CCD camera (Photometrics, Tucson, AZ, USA) controlled by the MetaMorph software (Universal Imaging, Downing Town, PA, USA).

4.2.22 Bioinformatic analysis

All DNA and protein sequences were retrieved from the public *Ustilago* database <http://www.broad.mit.edu>. DNA sequence analysis was done using the Clone Manager software. RT-PCR quantification was performed using Gel Doc2000: QuantifyOne 4.4.0 software (BIO-RAD). Northern results were quantified using the Image Quant software (Molecular Dynamics). Protein homologue searching was done using blast searching (<http://www.ncbi.nih.gov/blast/>).

Curriculum vitae

Personal information

Yan Zheng

born March 17, 1973 in Changchun, China

Education

1992-1996 Shanghai Railway University,
Shanghai, China

2000-2003 College of Life Science, Jilin University,
Changchun, China

2004-2007 PhD work at Max Planck Institute for
Terrestrial Microbiology, Marburg, Germany

Dissertation

PhD thesis topic: Identification of transcriptional regulators
for the *Ustilago maydis mig* genes.

Under the supervision of Dr. Christoph Basse

Acknowledgements

This thesis is submitted to the Philipps University of Marburg in Germany as the written part required for the fulfillment of the Ph.D. degree. Dr. Christoph Basse supervised the project.

The research work was carried out in the laboratory of organismic interactions, Max Planck Institute for Terrestrial Microbiology (Marburg), from May 2004 to September 2007.

I would like to thank Dr. Christoph Basse for the opportunity to do the work in his lab, for the interesting topic and for his ingenuity.

I would like to thank Prof. Dr. Regine Kahmann, head of the department of organismic interactions, who received my application for a position at Max Planck Institute for Terrestrial Microbiology and recommended it to Dr. Christoph Basse.

I thank Jan Farfsing, Kathrin Auffarth, Jan Kief and E. Kaya for all the contributions they have brought to me during this project.

My special thanks go to Dr. Michael Mahlert and Jan Kief for their patient proofreading for my thesis.

My special appreciation goes to my wife; I could not finish my Ph.D. study without her understanding and contributions for my family.

My gratitude goes to the referees that are serving as judge of my Ph.D. work, Prof. Dr. Regine Kahmann, Prof. Dr. Erhard Bremer, Prof. Dr. Hans-Ulrich Mösch and Prof. Dr. Alfred Batschauer.
