# Synthesis, Characterization and Application of Phosphazenyl Phosphines 

Dissertation

Zur Erlangung des Doktorgrades der Naturwissenschaften
(Dr. rer. nat.)

dem Fachbereich Chemie<br>der Philipps-Universität Marburg (Hochschulkennziffer 1180)

vorgelegt von

Sebastian Wagner
(M.Sc.)
aus Tegernsee

Marburg/Lahn 2023

Die vorliegende Arbeit wurde in der Zeit von Januar 2019 bis März 2023 unter der Leitung von Herrn Prof. Dr. Jörg Sundermeyer am Fachbereich Chemie der Philipps-Universität Marburg angefertigt.

Vom Fachbereich Chemie der Philipps-Universität Marburg (Hochschulkennziffer: 1180) als Dissertation angenommen am: 24.03.23

Erstgutachter: Prof. Dr. Jörg Sundermeyer
Zweitgutachter: Prof. Dr. Eric Meggers

Tag der mündlichen Prüfung: 25.05.2023

## Erklärung

Ich erkläre, dass eine Promotion noch an keiner anderen Hochschule als der Philipps-Universität Marburg, Fachbereich Chemie versucht wurde.

Hiermit versichere ich, dass ich die vorliegende Dissertation:
"Synthesis, Characterization and Application of Phosphazenyl Phosphines"
ohne unerlaubte Hilfe Dritter angefertigt und andere als die in der Dissertation angegebenen Hilfsmittel nicht benutzt habe. Alle Stellen, die wörtlich oder sinngemäß aus veröffentlichten oder unveröffentlichten Schriften entnommen sind, habe ich als solche kenntlich gemacht. Dritte waren an der inhaltlich-materiellen Erstellung der Dissertation nicht beteiligt; insbesondere habe ich hierfür nicht die Hilfe eines Promotionsberaters in Anspruch genommen. Kein Teil dieser Arbeit ist in einem anderen Promotions- oder Habilitationsverfahren der Antragstellerin oder des Antragsstellers verwendet worden. Mit dem Einsatz von Software zur Erkennung von Plagiaten bin ich einverstanden.

Marburg, den 24.03.23

Because the universe was full of ignorance all around and the scientist panned through it like a prospector crouched over a mountain stream, looking for the gold of knowledge among the gravel of unreason, the sand of uncertainty and the little whiskery eight-legged swimming things of superstition.

Terry Pratchett, Witches Abroad

## Danksagung

Als erstes Danke ich Prof. Dr. Jörg Sundermeyer, der es mir ermöglichte diese Arbeit in seinem Arbeitskreis anzufertigen und mir bei Fragen und Problemen immer zur Seite stand.

Ich möchte auch Prof. Dr. Eric Meggers für die Übernahme des Zweitgutachtens danken sowie Prof. Dr. Andreas Seubert für die Teilnahme an der Prüfungskommission.

Großer Dank geht auch an die Serviceabteilungen der Universität Marburg für die Durchführung von unzähligen Messungen. Besonderer Dank geht an Frau Xie für die Durchführung und Unterstützung der zahlreichen NMR Experimente.

Ein besonderer Dank gilt der Arbeitsgruppe Sundermeyer, besonders meinem Boxenpartner Eugen, der auch die Strukturlösungen meiner Kristalle übernommen hat. Danke an die Besucher des Chez Ambros: Igor, Morten, Olaf, Eugen und Kevin für die vielen Spieleabende. Auch dem restlichen und ehemaligen Arbeitskreismitgliedern: Marwa, Alex, Simon, Tobi, Marius K., Lisa, Subhankar und Ahmed sowie den zahlreichen Vertiefern will ich danken für den angenehmen und immer witzigen Laboralltag.

Schließlich möchte ich meiner Familie, insbesondere meinen Eltern, meinen herzlichen Dank für ihre unerschütterliche Unterstützung und Ermutigung aussprechen. Ihre ständige Motivation und ihr Glaube an mich waren eine treibende Kraft, und ich bin für ihre Präsenz in meinem Leben für immer dankbar.

Danke, dass ihr alle Teil dieser Reise mit mir wart!

## Abbreviations

| $t$ Bu-ind | 1-tert-butyl-indenyl |
| :---: | :---: |
| ad | Adamantyl |
| BIG | $N-N^{\prime}$-bis(imidazolyl)guanidine |
| CAAC | Cyclic alkylaminocarbene |
| CDP | Carbodiphosphorane |
| COD | Cyclooctadien |
| CPCM | Conductor-like polarizable continuum model |
| cy | Cyclohexyl |
| DABCO | 1,4-Diazabicyclo(2.2.2)octane |
| DACN | 1,8-Bis(bis(diisopropylamino)cyclopropeniminyl)naphthalene |
| DBU | 1,8-Diazabicyclo(5.4.0)undec-7-ene |
| DCM | Dichloromethane |
| DFT | Density functional theory |
| DIPEA | Diisopropylethylamine |
| Dipp | Diisopropylphenyl |
| DMA | Dimethylamine |
| DMAN | 1,8-Bis(dimethylamino)naphthalene |
| DMAP | 4-Dimethylaminopyridine |
| DME | Dimethoxyethane |
| DMF | Dimethylformamide |
| DMSO | Dimethylsulfoxide |
| eq | Equivalent |
| ESI | Electron spray ionisation |
| FT-ICR | Fourier-transform ion cyclotron resonance |
| GB | Gas phase basicity |
| HMPA | Hexamethylphosphorus acid trisamide |
| HOMO | Highest occupied molecular orbital |

## 1 Introduction

### 1.1 Acids and Bases

The concept of acids and bases is fundamental to our understanding of modern chemistry and as such, it is one of the first concepts taught in the curriculum of most schools. [1] Traditionally S. Arrhenius is credited with the first modern definition of acid base theory for which he received the Nobel Prize in chemistry in 1903. ${ }^{[2-4]}$ He defined an acid as a substance that dissociates in water to form hydrogen $\left(\mathrm{H}^{+}\right)$ions (1) and a base a substance that dissociates in water to form hydroxide $\left(\mathrm{OH}^{-}\right)$ions (2). Salts are the result of the neutralization reaction between an acid and a base (3) (Scheme 1.1).

Scheme 1.1: Definition of acids (1), bases (2) and salts (3) according to Arrhenius.

This model is constricted only to aqueous solutions and substances that can release $\mathrm{OH}^{-}$ions. To accommodate these issues,BrøNsTED and Lowry defined in 1923 an acid as a substance that can donate a proton and bases as substances that can accept a proton. ${ }^{[5][]]}$ This definition can be applied to non-aqueous systems by the generation of corresponding conjugated acid base pairs (Scheme 1.2).

$$
\mathrm{HA}+\mathrm{B} \rightleftharpoons \mathrm{~A}^{-}+\mathrm{BH}^{+}
$$

Scheme 1.2: Reaction of an acid (HA) and a base (B) to form the corresponding conjugate acid base pair $\left(\mathrm{BH}^{+}\right.$and $\left.\mathrm{A}^{-}\right)$.

LEWIS proposed a different definition of acids and bases in the same year. ${ }^{[7]}$ He defined acids as substances with empty orbitals capable of accepting an electron pair from a base and bases as donors of said electron pairs. Together, they form an acid-base adduct pair. Therefore, the BRøNSTED concept can be interpreted as a special case of the Lewis concept. Chemistry is the study of matter and the Arrhenius concept can be viewed with the matter (protons in aqueous media) as a focus, while BRøNSTED-LOWRY and LEwis both fundamentally describe a process, the donation, or acceptance, of a proton or electron pair. Therefore, they can be seen as a process driven concept (Figure 1.1). (8)

Figure 1.1: Relationship between different definitions of acid-base concepts.

An extension to these concepts is the HSAB (hard and soft acid and base) principle, popularized by Pearson in 1943. ${ }^{[9]}$ He proposes a distinction between hard and soft acids and bases, where hard refers to small, highly charged and weakly polarizable species, while soft refers to big, low charged and easily polarizable species. Soft acids will form more stable bonds with other soft bases than they will with hard bases all other factors being equal. This means, that hard acids and bases will form more ionic bonds and soft acids and bases will form more covalent bonds. This concept can be useful for determining the strength of a Lewis acid-base adduct. Other methods for categorizing the relationship between acids and bases by Usanovich, Lux and Flood exist, but are limited by their niche applicability. [10-12]

### 1.1.1 Quantifying the Strength of Acids and Bases

In order to quantify the strength of Brønsted acids the $\mathrm{p} K_{a}$ value is typically utilized. It can be obtained by calculating the equilibrium constant $K_{a}$ from the dissociation reaction of an acid into a proton and its conjugate base (Scheme 1.3).

$$
\mathrm{HA} \rightleftharpoons \mathrm{~A}^{-}+\mathrm{H}^{+}
$$

Scheme 1.3: Dissociation of an acid (HA) into a proton $\left(\mathrm{H}^{+}\right)$and its conjugate base ( $\mathrm{A}^{-}$).

The equilibrium constant is defined as:a

$$
\begin{equation*}
K_{a}=\frac{\left[A^{-}\right]\left[H^{+}\right]}{[H A]} \tag{1.1}
\end{equation*}
$$

The $\mathrm{p} K_{a}$ value is defined as the negative decadic logarithm of this equilibrium constant:

$$
\begin{equation*}
p K_{a}=-\log K_{a} \tag{1.2}
\end{equation*}
$$

It is related to the pH value with the following equation:

$$
\begin{equation*}
p H=p K_{a}+\frac{\left[A^{-}\right]}{[H A]} \tag{1.3}
\end{equation*}
$$

[^0]The strength of bases is commonly defined by the $\mathrm{p} K_{B H^{+}}$value which is the $\mathrm{p} K_{a}$ value of the conjugate acid. In principle it can be said, that the lower the $\mathrm{p} K_{a}$ value the stronger the acid and the higher the $\mathrm{p} K_{B H^{+}}$value the stronger the base. Table 1.1 shows an overview of several acids and bases and their respective $\mathrm{p} K_{a}$ values in water.

Table 1.1: Overview of $\mathrm{p} K_{a}$ values of different substances in water. [13-15]

| Entry | Compound | $\mathrm{p} K_{a}\left[\mathrm{H}_{2} \mathrm{O}\right]$ | Entry | Compound | $\mathrm{p} K_{a}\left[\mathrm{H}_{2} \mathrm{O}\right]$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | 2.2 | 5 | $\mathrm{PhNO}_{2} \mathrm{H}^{+}$ | -12.4 |
| 2 | $t-\mathrm{BuOH}$ | 20 | 6 | $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ | -14.7 |
| 3 | HCN | 9.1 | 7 | $\mathrm{MeCNH}^{+}$ | -10.7 |
| 4 | $\mathrm{PyrH}^{+}$ | 5.2 | 8 | HCl | -2.2 |

Experimentally, these values can be obtained by competition reaction of one reactant of known $\mathrm{p} K_{a}$ value and one reactant of unknown $\mathrm{p} K_{a}$ value (Scheme (1.4).

$$
\mathrm{HA}+\mathrm{B} \stackrel{\mathrm{~K}}{\rightleftharpoons} \mathrm{~A}^{-}+\mathrm{BH}^{+}
$$

Scheme 1.4: Competition reaction between two reactants with equilibrium constant K .

In an equilibrium, the protochemical potentials of these two reactants are identical. Therefore, the equilibrium constant can be calculated and with it the $\mathrm{p} K_{a}$ value of the unknown reactant. Experimentally, the equilibrium constant can be determined by NMR spectroscopy ${ }^{16]}$, UVVis spectroscopy ${ }^{[17]}$ or potentiometry ${ }^{[18]}$ and the $\mathrm{p} K_{a}$ value of the unknown compound may be calculated according to equation 1.4. In order to guarantee the accuracy of these experimental methods, the $\mathrm{p} K_{a}$ value of the reference base should be within one $\mathrm{p} K_{a}$ unit of the unknown base.

$$
\begin{equation*}
p K_{a}=p K_{a}(r e f)-\log K=p K_{a}(\text { ref })-\log \frac{\left[A^{-}\right] *\left[B H^{+}\right]}{[H A] *[B]} \tag{1.4}
\end{equation*}
$$

The scale in water begins to show its limitations when strong acids or bases are employed, because they will completely disassociate in water to form $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$ions. It is not possible to differentiate among the relative strengths or weaknesses of stronger acids or bases than the solvents conjugate acid or base. This is called the leveling effect of water. ${ }^{[19]}$ Self-consistent solvent scales have been adapted by the scientific community to alleviate this issue. Commonly used scales are DMSO ${ }^{[20]}$, MeCN ${ }^{[2]}$ and THF. ${ }^{[22]}$ Because of intramolecular hydrogen bonding and other solvatisation effects, these scales can not be directly compared with each other. They can, however, be correlated if the solvents are comparable like THF and MeCN with values in MeCN being generally higher than in THF. [23]

### 1.1.2 Gas Phase Basicity and Proton Affinity of Bases

In order to assess the strengths of bases independent of solvent effects, the gas phase basicity and the proton affinities can be quantified. The gas phase basicity (GB) is calculated as the Gibbs free energy of the reaction:

$$
\mathrm{B}+\mathrm{H}^{+} \rightarrow \mathrm{BH}^{+}
$$

so that:

$$
\begin{equation*}
\Delta G=G_{(B H)}-\left[G_{(B)}+G_{\left(H^{+}\right)}\right] \tag{1.5}
\end{equation*}
$$

Proton affinities can be calculated as the enthalpy of the aforementioned reaction.

$$
\begin{equation*}
P A=H_{\left(B H^{+}\right)}-\left[H_{(B)}+H_{\left(H^{+}\right)}\right] \tag{1.6}
\end{equation*}
$$

The GB can be experimentally measured by Fourier-transform ion cyclotron resonance (FTICR) mass spectrometry of an analyte and a reference base (Scheme 1.5). [24][25]

$$
\mathrm{B}_{2}+\mathrm{B}_{1} \mathrm{H}^{+} \stackrel{\Delta \Delta \mathrm{G}_{\mathrm{b}}}{\rightleftharpoons} \mathrm{~B}_{2} \mathrm{H}^{+}+\mathrm{B}_{1}
$$

Scheme 1.5: Competition reaction between two bases in the gas phase.

With

$$
\begin{gather*}
\Delta \Delta G_{b}=\Delta G_{b}\left(B_{2}\right)-\Delta G_{b}\left(B_{1}\right)=-R T * \ln K  \tag{1.7}\\
K=\frac{p\left(B_{1}\right) * I\left(B_{2} H^{+}\right)}{p\left(B_{2}\right) * I\left(B_{1} H^{+}\right)} \tag{1.8}
\end{gather*}
$$

The ratio of the partial pressures of the neutral species can be measured by a pressure gauge and the mixture of the charged gases can be measured by comparing the intensities of the ions in the mass spectrum after a sufficient equilibrium has been reached. ${ }^{[24][25]}$ Other methods such as high pressure mass spectrometry (HPMS) have also been successfully employed. [26]

### 1.2 Different Types of Bases

A preparative chemist performing a reaction requiring a base can choose between three different substance classes: a) Ionic metal bases such as NaOH , b) Organometallic bases such as $n-\mathrm{BuLi}$ and c ) organic bases such as diisopropylethylamine (DIPEA). Ionic metal bases are convenient in their usage as they are usually cheap and easy to handle. NaOH for example is a byproduct of the generation of chlorine gas from the electrolysis of $\mathrm{NaCl} .{ }^{[27]}$ They perform reasonably well for most applications but have limited solubility in most common organic solvents such as THF and DCM, often resulting in heterogeneous reaction conditions. [28] Organometallic bases in contrast are very soluble in organic solvents, however they are also very reactive leading to a decrease in selectivity. $n$ - BuLi for example will deprotonate THF at room temperature, releasing butane and ethylene as well as generating acetaldehyde. Reactions with $n$ - BuLi in THF are therefore carried out at low temperatures. ${ }^{[29]}$ They are often pyrophoric, which requires additional precautions, especially when used in large quantities. The third type of bases are organic bases with the simplest being substituted amines like the already mentioned DIPEA or triethylamine $\left(\mathrm{NEt}_{3}\right)$. They are versatile and easily soluble in most solvents but are limited in their applicability and have to be selected for a specific purpose. They can range from lightly basic amines to superbasic guanidines (Figure 1.2). [30]

Some organic bases are also prone to side reactions as they may react as nucleophiles, however this can be remedied by modifications on the amine backbone by increasing their steric hindrance and inhibiting nucleophilic attacks. Their nucleophilicity can also be exploited by employing them as nucleophilic catalysts instead of a base. [31] They are easily handled as they are not pyrophoric and easily removed from the reaction mixture by precipitation as a salt.

### 1.3 Superbases

### 1.3.1 Definition of Superbases

The scientific community has not yet reached a consensus of what constitutes a superbase, though several attempts to define them have been made. Caubère applies the term superbases only to bases resulting from the mixing of two or more bases leading to a new species with inherently new properties. His definition does not mean that a base is thermodynamically or kinetically stronger than another base, it only means that the properties of the new basic species surpasses that of its parts. ${ }^{[32]}$ Schlosser complements this by defining two types of superbases, CAUBÈRE's unimetal super bases and his own multimetal super bases (Scheme [1.6). ${ }^{[33]}$ This definition generally is applied to ionic metal containing bases which react under irreversible proton abstraction. ${ }^{[30]}$ IUPAC defines superbases as bases that possess a p $K_{B H^{+}}$value of LDA or higher. ${ }^{[34]}$ Sundermeyer proposes a threshold in the gas phase of $237.8 \mathrm{kcal} / \mathrm{mol}$ (DMAN) and of a p $K_{B H^{+}}$value of 25 in MeCN or 17 in THF (based on the value for TMGN). ${ }^{[35[36]}$ In this work we will use this definition going forward and $\mathrm{p} K_{B H^{+}}$ values will be, unless otherwise stated, given in MeCN.

### 1.3.2 Nitrogen Superbases

### 1.3.2.1 Schwesinger Bases

Nitrogen centered superbases are the most commonly known and most established class of superbases. SchWESINGER's phosphazene bases are the most readily commercially available representatives of this class of compounds. First introduced by Issleib in 1973 and later improved by SCHWESINGER these peralkylated (poly)iminophosphoranes are able to delocalize a positive charge over the whole of the phosphorus and nitrogen backbone. ${ }^{39]}$ They are referred to by a shortened notation $\left(R^{1}\right) P_{x}-R^{2}$ where $R^{1}$ is the substituent on the phosphazene core,
and $R^{2}$ is the substituent on the terminal imine group and X is the number of phosphorus atoms attached to phosphazenyl groups. The simplest of these bases (dma) $\mathrm{P}_{1}-\mathrm{Me}$ was already synthesized by ISSLEIB and shows a remarkable $\mathrm{p} K_{B H^{+}}$value of 27.6. SCHWESINGER improved upon this by substituting a $N$-t-butyl unit to the basic nitrogen site (Figure [1.3). [17] The increase of basicity by substitution of dimethylamino groups to pyrrolidino groups can be attributed to the higher electron density of the pyrrolidino nitrogen atom compared to the dimethylamino nitrogen. A more intense increase in basicity can be seen by the battery cell principle of SCHWESINGER. Each additional phosphazenyl unit increases the basicity by approximately 4 units, leading to the extremely basic (pyrr) $\mathrm{P}_{5}-t \mathrm{Bu}$ with a $\mathrm{p} K_{B H^{+}}$value of 46.9. SCHWESINGER remarks that including additional phosphazene units from (dma) $\mathrm{P}_{5}-t \mathrm{Bu}$ to (dma) $\mathrm{P}_{7}-t \mathrm{Bu}$ (not isolated) does not correspond to an increase in basicity, and indicates a levelling effect due to resonance saturation. ${ }^{40]}$ SCHWESINGER bases are not only remarkably basic, they are also easily stored as $\mathrm{HBF}_{4}$ salts. As such, they are insensitive to oxidation and hydrolysis. They are also not prone to react as nucleophiles because of their bulky backbone, unlike other organic amidine bases such as DBU. However, due to their extreme basicity, it can be challenging to liberate the free bases from their $\mathrm{HBF}_{4}$ salts. Another noteworthy aspect of these bases is, that through their big core, the resulting cations that are formed from protonation of these compounds are so large and sterically hindered, that it allows the generation of almost naked anions that are highly reactive. 41-43]

Figure 1.3: Overview of different Schwesinger bases ( $\mathrm{p} K_{B H^{+}}$values in MeCN ).

The astounding basicity of SCHWESINGER bases comes mostly through its iminophosphorane units, which are inherently hypercoordinated phosphorus (V) compounds. Because of the octet rule, they are only able to form four bonds. Additional bonds have to be formed from negative hyperconjugation. If we look at the MO scheme of a trisubstituted phosphine, the HOMO represents the lone pair of the phosphorus atom which undergoes a covalent $\sigma$-bond with the substituent. This represents the zwitterionic structure of $\mathrm{R}_{3} \mathrm{P}-\mathrm{X}$. Additionally, the antibonding $\pi^{*}$ orbitals of the LUMO can bond with non-bonding p orbitals of the substituent, which corresponds to a formal double bond $\mathrm{R}_{3} \mathrm{P}=\mathrm{X}(\mathrm{X}=\mathrm{O}, \mathrm{NR}, \mathrm{CHR})$ (Figure 1.4). This double bond character is decreased with increasing $\sigma$ - and $\pi$-donor ability of the substituent. If one compares the anionic charge of $\mathrm{R}_{3} \mathrm{P}^{+}-\mathrm{NR}^{\prime-}$ and $\mathrm{R}_{2} \mathrm{C}^{+}-\mathrm{NR}^{\prime-}$ (for $\mathrm{R}=\mathrm{Me}$ and $\mathrm{R}^{\prime}=$ Me ) the anionic charge is less efficiently stabilized on the iminophosphorane, because it is only stabilized by negative hyperconjugation of the empty $\sigma^{*}$ - or $\pi^{*}$-orbitals of the phosphonium ion. The iminium is, in contrast, stabilized by $\pi$-conjugation to the $\pi$-acceptor of the carbenium center. This means, that imines have inherently higher zwitterionic character than iminophosphoranes. If one substitutes the amino substituents on the iminophosphorane with further iminophosphorane groups however, the increase of $\sigma$ - and $\pi$-donor ability of the substituent decreases the polarizability of the $\mathrm{R}_{3} \mathrm{P}-\mathrm{NR}$ ' bond and therefore decreases the double bond character. This leads to an increase in the zwitterionic character, which in turn
stabilizes the positively charged phosphonium ion, leading to a higher basicity. The double degenerate LUMO of $2 \mathrm{e}^{*}$ symmetry (a linear combination of P-C $\sigma^{*}$ - and P 3 d -orbitals) may act as an $\pi$-acceptor orbital for $\pi$-backbonding in complexes of the form $\mathrm{PR}_{3}-\mathrm{M}$. [4]]

Figure 1.4: MO scheme of a $-\mathrm{PR}_{3}$ fragment. [45]

Synthetically, Schwesinger's bases can be derived from two building blocks, both starting from $\mathrm{PCl}_{5}$. By reaction of $\mathrm{PCl}_{5}$ with gaseous $\mathrm{Me}_{2} \mathrm{NH}$ in DCM a trisubstituted phosphonium chloride is generated which reacts with ammonia to yield the hydrochloride salt of the iminophosphorane (Scheme 1.7). Through subsequent deprotonation with KOMe in MeOH and distillation, the free iminophosphorane can be generated. The second building block $\mathrm{PCl}_{3}-\mathrm{N} t \mathrm{Bu}$ is generated by a condensation reaction of $t-\mathrm{BuNH}_{2}$ with $\mathrm{PCl}_{5}$. Combination of these two building blocks in THF and subsequent reaction with gaseous $\mathrm{Me}_{2} \mathrm{NH}$ yields the hydrochloride (dma) $\mathrm{P}_{2}-t \mathrm{Bu} \cdot \mathrm{HCl}$. Another deprotonation step with KOMe in MeOH yields the final product. ${ }^{[17]}$

Scheme 1.7: Synthetic pathway to (dma) $\mathrm{P}_{2}-t \mathrm{Bu}$.

### 1.3.2.2 Guanidines, Amidines and Proton Sponges

Another popular structural feature of many superbases are guanidines. Their basicity can be traced due to their resonance stability of the three nitrogen core from their conjugate acids. [46-48] The most commonly known guanidine superbase is $N, N, N^{\prime}, N^{\prime}, N^{\prime \prime}$-pentamethylguanidine (PMG) with a $\mathrm{p} K_{B H^{+}}$of 25.0 (Figure 1.5). Another example is 7 -methyl-1,5,7-triazabicyclo(4.4.0)dec-5-ene $\left(\mathrm{MTBD}, \mathrm{p} K_{B H^{+}}=25.4\right)$ which, through its cyclic constraint, forces the two tertiary amino groups into conjugation with the imino basicity center. Proton sponges such as DMAN (1,8-bis(dimethylamino)naphthalene) have been known since 1968 when ALDER first reported a huge increase in basicity through the methylation of 1,8diaminonaphtalene. The basicity increased from a $\mathrm{p} K_{B H^{+}}$of 6.4 to 12.3 (in water) for the final methylation step, which prompted an investigation into the nature of this phenomenon. ${ }^{49]}$ It was discovered, that the two basicity centers which are closely positioned near each other allow for an intramolecular exchange of protons. Additionally, the free base form of DMAN benefits from electronic repulsion of the nitrogen lone pairs which leads to a slight torsion of the naphtalene core and a subsequent reduction in its aromatic character. Through protonation this repulsion is removed, which makes it kinetically favored. Later on, Alder, Schwesinger and Verkade improved on this theory by a combination of steric strain, stronger intramolecular hydrogen bonding (IHB) or destabilization of the neutral molecule. ${ }^{[50-53]}$ Through the implementation of a guanidine moiety, a proton sponge that can be considered a superbase was obtained in TMGN ( $\mathrm{p} K_{B H^{+}}=25.1$ ) which outpaces planar amidines like DBU ( $\mathrm{p} K_{B H^{+}}=$ 24.3). ${ }^{[36]}$ SCHWESINGER's vinadimine type superbases outpace this by several orders of magnitude ( $\mathrm{p} K_{B H^{+}}=31.9$ ) by forcing more nitrogen atoms into conjugation with the $N$-alkylimino functionality. [35] Variations of the TMGN proton sponge by substitution of the guanidine moiety with a phosphazene moiety lead to even higher basicities $\left(\mathrm{p} K_{B H^{+}}=40.2\right) .{ }^{[54]}$

Figure 1.5: Overview of different superbases with guanidine, cyclopropenimine functions. ( $\mathrm{p} K_{B H^{+}}$in MeCN )

Proton sponges with a cyclopropenimine moiety have also been reported with basicities comparable to TMGN. ${ }^{[55]} N, N^{\prime}$-bis(imidazolyl)guanidine bases (BIG bases) have also been reported that possess a fusion of guanidine and imidazol moieties. These bases are very large, which enable an efficient delocalization of the positive charge over the whole molecule, leading to
high basicities $\left(\mathrm{p} K_{B H^{+}}=36.9\right) .{ }^{[56]}$ DACN can be prepared by a simple two-step procedure by the reaction of four equivalents of diisopropylamine with one equivalent of tetrachlorocyclopropene followed by the addition of one equivalent of naphthalene-1,8-diamine to generate the hydrochloride salt (Scheme 1.8). This hydrochloride can be recrystallized and subsequently deprotonated with KHMDS in toluene to generate the free base DACN. Alternatively, the hydrochloride salt may be ion exchanged to the $\mathrm{HBF}_{4}$ salt to allow for better storage, as the tetrafluoroborate is less hygroscopic. ${ }^{[57] 58]}$

Scheme 1.8: Synthetic pathway to DACN starting from naphtalene-1,8-diamine and tetrachlorocyclopropene.

The guanidine proton sponge TMGN is prepared similarly. First, the VILSMEYER salt $\left(\mathrm{NMe}_{2}\right)_{2} \mathrm{CCl}$ has to be prepared from phosgene and tetramethylurea. Afterward, it is reacted with naphthalene-1,8-diamine to generate the hydrochloride salt of the bisguanidine (Scheme 1.9). This resulting solution is treated with aqueous NaOH to deprotonate and separate triethylammoniumchloride from the reaction mixture. The bisguanidinium hydrochloride can then be deprotonated and isolated by treatment with aqueous KOH ( $30 \%$ ), extraction with MeCN and washing with hexane. ${ }^{36]}$

Scheme 1.9: Synthetic pathway to TMGN starting from naphtalene-1,8-diamine and $\left(\mathrm{NMe}_{2}\right){ }_{2} \mathrm{CCl}$.

For the preparation of BIG bases, $N$-alkylguanidinium iodides have to be prepared by reaction of an isothiouronium salt $\left(\left[\mathrm{MeS}-\mathrm{C}\left(\mathrm{NH}_{2}\right)_{2}\right] \mathrm{I}\right)$ with the corresponding amine. These are then reacted with a 2-chloroimidazolium salt and KF in MeCN (Scheme 1.10). The resulting salt is subsequently treated with aqueous $\mathrm{NaBF}_{4}$ to isolate the tetrafluoroborate salt. By treatment with $\mathrm{KO} t \mathrm{Bu}$ the free base form can be generated. ${ }^{[56]}$

Scheme 1.10: Synthetic pathway to $i \operatorname{Pr}$-BIG from $\left[\mathrm{MeS}-\mathrm{C}\left(\mathrm{NH}_{2}\right)_{2}\right] \mathrm{I}$ and 2-chloro-1,3diisopropylimidazolium tetrafluoroborate.

### 1.3.3 Carbon Superbases

Molecules with a carbon atom as a basicity center like $N$-heterocyclic carbenes (NHC), P-ylide substituted phosphines (YPhos) ${ }^{[59]}$ and carbodiphosphoranes (CDP) have been established mostly as strong donor ligands for various applications such as gold catalyzed aminations of alkynes ${ }^{[60]}$ and palladium catalyzed ${ }^{[59[6] \mid 62]}$ cross couplings or their usage as chelating ligands for OLED emitters (Figure [1.6). .63]

N -heterocyclic carbenes
NHC

Ylid functionalized phosphine
YPhos

Figure 1.6: Different superbases with a carbon as basicity center.

Since the inception of CDPs by Ramirez et al. in 1961 with the synthesis of hexaphenylcarbodiphosphoran ${ }^{[64]}\left(\mathrm{Ph}_{6}-\mathrm{CDP}\right)$ and subsequent synthesis of $\mathrm{Me}_{6}-\mathrm{CDP}{ }^{[65]}$ and dma ${ }_{6}-\mathrm{CDP}{ }^{[66]}$ the chemistry of CDPs grew in focus of the scientific community. Frenking describes the bonding situation of CDPs as "divalent carbon(0) compounds in which the valence electrons of carbon remain as two lone pairs of electrons". "67] In 2015 Leito et al. postulated a theoretical gas phase basicity of $350 \mathrm{kcal} / \mathrm{mol}$ for guanidino phosphorus carbenes. ${ }^{[68]}$ This prompted an investigation to apply Schwesinger's battery cell principle to CDPs. In 2019 UllRICH et al. succeeded in synthesizing the to date strongest CDP bases (pyrr) ${ }_{6}$ - CDP and $\operatorname{sym}(\mathrm{tmg})_{2}(\mathrm{dma})_{4}$-CDP (Figure 1.7) with a GB of $282.2 \mathrm{kcal} / \mathrm{mol}$ and $287.2 \mathrm{kcal} / \mathrm{mol}$ for the first protonation step respectively. ${ }^{[69]}$ Ylidic basicity centers were also applied to the concept of proton sponges. 1,8 - $\operatorname{Bis}$ (methanyliden(hexamethyltriamino)- phosphoranyl)naphthaline (MHPN) was synthesized and possesses a GB of $277.8 \mathrm{kcal} / \mathrm{mol}$ and a $\mathrm{p} K_{B H^{+}}$of 33.2. The theoretical analogue $\mathrm{P}_{2}$-MHPN exhibits a GB of $294.7 \mathrm{kcal} / \mathrm{mol}$, but was not yet isolated. 70 ] Gessner's ylide substituted phosphines have not been thoroughly investigated about their basic properties. The spotlight for these compounds lies more in their ability to effectively donate electron density in a ligand role. They have excelled in this role in various applications and surpass NHCs and classical tertiary phosphines. [71-73]

Figure 1.7: Overview of different carbon superbases $\left(\mathrm{p} K_{B H^{+}}\right.$in MeCN$)$. 69 [7]

Synthetically, these superbasic CDPs are prepared according to a modified procedure first published by Appel for the synthesis of dma ${ }_{6}$-CDP. [66] The synthesis of bis(di(pyrrolidin-1-yl)phosphaneyl)methane (Scheme (1.11) was accomplished in a one pot reaction from one equivalent of bis(dichlorophosphino)methane with eight equivalents of pyrrolidine. This compound is unstable toward vacuum distillation and was therefore used without further purification in an oxidative imination with $\mathrm{CCl}_{4}$ and three more equivalents of pyrrolidine. Afterward, the resulting hydrochloride was transformed to its $\mathrm{HBF}_{4}$ salt. Deprotonation was accomplished by reaction with KHMDS in THF. For the bisylidic proton sponge MHPN, first 1,8-bis(bromomethyl)naphthalene was reacted with two equivalents of tris(dimethylamino)phosphine to generate the hydrobromide salt of the bisylide. Through deprotonation with benzyl potassium in THF the bisylide MHPN could be generated. Gessner's YPhos ligands are generated from commonly available alkylphosphonium bromides by deprotonation with a metal base such as $n-\mathrm{BuLi}$ and subsequent reaction with a dialkylchlorophosphine. This bisylide can then be deprotonated by $\mathrm{KO} t \mathrm{Bu}$ to generate the ylide substituted phosphine.

Scheme 1.11: Synthetic pathway to pyrr $_{6}-$ CDP $^{[69]}$, MHPN ${ }^{[70]}$ and joYPhos. 71$]$

### 1.3.4 Phosphorus Superbases

The earliest representatives of superbases, where the phosphorus atom acts as the basicity center, are Verkade's proazaphosphatranes. ${ }^{[74]}$ Originally intended as double ended ligands for connecting metal species via the bridgehead atoms, they found considerable success in the field of organocatalysis. ${ }^{[75]}$ They are bicyclic, non-ionic bases which, when protonated are stabilized by a trans-annular PN bond formation as well as through negative hyperconjugation of the NR groups (Figure 1.8). These bases are stronger than $\mathrm{P}_{1}$ phosphazenes with $\mathrm{p} K_{B H^{+}}$ values of 33.3 but weaker than $\mathrm{P}_{2}$ phosphazenes. ${ }^{[76]}$ This trans-annular PN bond formation can be observed by comparing the NMR spectra of the free base and its protonated counterpart. While in the free base no axial ${ }^{3} J_{(P, H)} \mathrm{PNCH}_{2}$ coupling is observed in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$, it is clearly visible with a coupling constant of 4.7 Hz in the protonated form. Similar observations can be made for the ${ }^{2} J_{(P, C)}$ coupling constant of $\mathrm{PN}_{\mathrm{ax}} \mathrm{C}$ of 6.7 Hz . ${ }^{[74]}$ Iminophosphoranes of VERKADE's proazaphosphatranes also exist, but exhibit a considerably lower $\mathrm{p} K_{B H^{+}}$of 29.0. ${ }^{[77]}$ Verkade also reports the synthesis of an analogue of $\mathrm{P} t \mathrm{Bu}_{3}$ where one tert-butyl substituent was replaced by a proazaphosphatrane The resulting phosphines are very electron rich and can be utilized as ligands for palladium catalyzed cross coupling reactions. ${ }^{[79[80]}$ Dielmann and coworkers recently published the synthesis of a series of pyridinylidenaminophosphines (IAP). ${ }^{[8]}$ They approach, not from a desire to design superbasic compounds, but from the viewpoint of designing highly electron rich donor ligands for various applications. They offer cheap and simple synthetic routes (Scheme 1.8) with an easily tune-able selection of R substituents at the pyridine $N$-atom as well as offer different degrees of substitution at the central phosphorus atom. In 2022, they were able to synthesize the previously elusive tris(tetramethylguanidinyl)phosphine $\left(\mathrm{P}(\mathrm{tmg})_{3}\right)$ which possesses a $\mathrm{p} K_{B H^{+}}$of 32.7 . ${ }^{[82]}$ They also report the synthesis of dialkyl(1,3-diarylimidazolin-2-ylidenamino) phosphines that possess an aromatic backbone similar to BuchwalD's famous phosphine ligands. ${ }^{[83[84]}$ Ullrich et al. reported the synthesis of the to date strongest uncharged phosphorus bases with trisphosphazenyl phosphines. ${ }^{[85[86]}$ They are derived from Schwesinger's phosphazene bases but have undergone a formal reductive elimination of a nitrene.

Figure 1.8: Proazaphosphatrane (left), Pyridinylidenaminophosphines, tristetramethylguanidinylphosphine (middle) and trisphosphazenylphosphines (right).

[^1]These phosphazenyl phosphines (PAP) are even stronger than Schwesinger's phosphazene bases with the same number of phosphorus atoms, as was previously theoretically predicted. ${ }^{[87]}$ With a $\mathrm{p} K_{B H^{+}}$value of 37.2 in THF, $\mathrm{dmaP}_{4} \mathrm{P}$ is one of the strongest uncharged superbases, closely followed by $\mathrm{dmaP}_{3} \mathrm{P}$ with a $\mathrm{p} K_{B H^{+}}$value of 34.9 (Corresponding to 43.1 in MeCN for $\mathrm{dmaP}{ }_{3} \mathrm{P}$ and 45.6 for the asymmetric $\left.\mathrm{dmaP}_{4} \mathrm{P}\right)$. ${ }^{[23]}$ Synthetically, VERKADE's proazaphosphatranes are prepared by reaction of an alkylaldehyde with $N^{\prime}, N^{\prime}$-bis(2-aminoethyl)ethane-1,2diamine and subsequent reduction of the intermediate aldimine with $\mathrm{NaBH}_{4}$ (Scheme 1.12). The ring closure was achieved by reaction with $\mathrm{PCl}\left(\mathrm{NMe}_{2}\right)_{2}$ to afford the hydrochloride salt. The free base can be liberated by reaction with $\mathrm{KO} t \mathrm{Bu} .{ }^{[88]}$

Scheme 1.12: Synthetic pathway to a proazaphosphatrane (top) and trans-annular P-N bonding (bottom). 8 [8]

Trisphosphazenyl phosphines are prepared similarly. $\mathrm{PCl}\left(\mathrm{NEt}_{2}\right)_{2}$ reacts with an iminophosphorane to generate the trisubstituted hydrochloride $\mathrm{P}_{3} \mathrm{P} \cdot \mathrm{HCl}$ which is converted to its $\mathrm{HBF}_{4}$ salt with $\mathrm{NaBF}_{4}$ (Scheme 1.13). $\mathrm{PCl}\left(\mathrm{NEt}_{2}\right)_{2}$ is used as both an auxiliary base as well as the phosphorus source for this reaction. Liberation of the free base by deprotonation with KHMDS yields the final PAP in $88 \%$ yield. VERKADE's proazaphosphatrane phosphines are synthesized by Kirsanov reaction with iodide to generate the phosphonium iodide and subsequent reaction with ammonia to the iminophosphorane. Deprotonation and reaction with a chlorophosphine generates the final phosphine. ${ }^{[85]}$ DIelmann's IAP can be synthesized by alkylation of the aminopyridine and subsequent reaction with a chlorophosphine to generate monoIAPs. TrisIAPs are prepared by reaction of the aminopyridine with $\mathrm{PCl}_{3}$ and subsequent generation of the IAP- $\mathrm{HBF}_{4}$ salt (Scheme 1.14, top). Deprotonation with KHMDS results in the free base IAP. Trisubstituted $\mathrm{P}(\mathrm{tmg})_{3}$ was prepared by a mixture of $\mathrm{tmg}-\mathrm{H}, \mathrm{PCl}_{3}$ and $\mathrm{P}\left(\mathrm{NMe}_{2}\right)_{3}$ in a 3:2:1 ratio. This generates $\mathrm{PCl}\left(\mathrm{NMe}_{2}\right)_{2}$ in situ, which acts as both an auxiliary base and the phosphorus source and yields the hydrochloride $\mathrm{P}(\mathrm{tmg})_{3} \cdot \mathrm{HCl}$ in quantitative yield (Scheme [1.14, bottom). Subsequent deprotonation with KHMDS yields the free base. ${ }^{[82]}$

Scheme 1.14: Synthetic pathway to a mono- and trisIAP ${ }^{[81]}$ (top) and $\mathrm{P}(\mathrm{tmg})_{3}$ (bottom). [82]

### 1.4 Measuring Donor Abilities of Ligands

Basicity is only one aspect of a molecule's properties, and there are other quantifiable parameters that can be considered. Phosphines especially have been utilized mostly as ligands for transition metal catalysis and as such several metrics to measure and compare these compounds have been developed. The Tolman electronic parameter (TEP) describes the donor-acceptor ability of a ligand as a measure of the $A_{1}$ vibrational mode of the carbonyl bond of a tetrahedral complex of the form $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ (Figure [1.9). ${ }^{89}$ [90] The shift in the frequency of this vibrational mode upon coordination from free CO to $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ can be explained by $\pi$-backbonding from the ligand to the metal. The metal forms a $\pi$ bond by donating electron density from its d-orbitals into the anti-bonding $\pi^{*}$ orbital of CO. This
strengthens the metal-carbonyl bond and thus weakens the carbon-oxygen bond. Therefore, less energy is needed to excite the $A_{1}$ vibrational mode, thus decreasing the frequency. If the electron density on the metal is increased through $\sigma$-donation from a ligand, this density is transferred into the antibonding $\pi^{*}(\mathrm{CO})$ orbitals, thus increasing the CO bond length and decreasing the CO stretching mode even more. If the electron density is decreased by ligands acting as competing $\pi$-backdonors to CO , the frequency of the $A_{1}$ vibrational mode is increased instead.

Figure 1.9: $A_{1}$ vibrational mode (left) and an example of $\sigma$-donation of a ligand.

The TEP does, however, have its limitations Some compounds won't form a tetraedral $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complex and as such cannot be directly compared. Additionally, because of the extremely high toxicity of nickel carbonyls alternatives have been sought out. For NHCs there have been TEP analogues with complexes of the type $\left[\mathrm{L}-\mathrm{M}(\mathrm{CO}){ }_{2} \mathrm{Cl}\right]$ for $\mathrm{M}=\mathrm{Rh}$, Ir. ${ }^{[2]}$ HUYNH proposed a ligand electronic parameter based on ${ }^{13} \mathrm{C}$-NMR chemical shifts for NHC complexes of palladium (II). ${ }^{[93[94]}$ BERTRAND utilizes the ${ }^{31} \mathrm{P}$-NMR chemical shifts of carbene-phosphinidine adducts as an indicator instead. ${ }^{[95]}$ GANTER utilizes the chemical shift of ${ }^{77} \mathrm{Se-NMR}$ in NHC-Se adducts, as well as the ${ }^{1} J_{(C, S e)}$ coupling constants of azolium selenide salts. ${ }^{[66[97]}$ The TEP also suffers from inconsistencies because of mode-mode coupling between $\mathrm{M}-\mathrm{C}$ and CO vibrations that can range up to $200 \mathrm{~cm}^{-1}[88]$ and because the electronic bonding mechanism is more complicated than described by Tolmand. 90 Nonetheless, the TEP is a popular parameter because it is easily measured and gives a good approximation of donor abilities, although it is often coupled with other methods. Similarly to NHCs, selenides of phosphines are easily obtainable by reaction of the free phosphine with gray selenium. The resulting ${ }^{1} J_{(P, S e)}$ coupling constants as well as the chemical shifts of the ${ }^{31} \mathrm{P}$-NMR and ${ }^{77}$ SeNMR can be used to determine the donor ability of ligands. The ${ }^{1} J_{(P, S e)}$ coupling constant is mostly influenced by the s-character of the phosphorus selenium bond, which can be correlated to the electronic properties of the phosphine. ${ }^{[100]}$ Electron withdrawing groups increase the s-character of the phosphorus lone pair, therefore increasing the coupling constant according to Bent's rule. ${ }^{[101]}$ Electron rich groups in turn, decrease the coupling constant. ${ }^{[102]}$ This correlation is not without faults, as increased sterical hindrance on the phosphorus atom may also result in a decrease of s-character of the lone pair. [103[104] Additionally, it is known that intramolecular hydrogen bonding may affect the coupling constant and bulky aryl substituents on phosphorus atoms have been known to cause an increase in ${ }^{1} J_{(P, S e)}$ coupling constants that do not necessarily correlate with its electronic properties. ${ }^{[105 /[107]}$ Sterical properties of ligands can be described by the cone angle $\theta$ of a ligand, originally described by Tolman for nickel phosphine complexes. ${ }^{[8]}$ The cone angle is the apex angle of a cylindrical cone

[^2]centered $2.28 \AA$ from the center of the phosphorus atom which touches the van-der-Waals radii of the outermost atoms. 90$]$ It is, however, limited by the restriction of the M-L bond length being fixed at $2.28 \AA$ and inaccuracies occur for non-phosphine or asymmetric ligands. Closely related is the solid angle $\omega$, which can be described as a measure of the 'shadow' cast by an atom or group of atoms when placed relative to an apex atom, 'a light source' [108] They are not bound by a fixed L-M bond length and can be calculated from a crystal or a computationally generated structure. The disadvantage of the solid angle approach is, that it treats the ligand as 'frozen', which induces inaccuracies, as ligands are often able to almost freely rotate along low rotational barriers. ${ }^{[109][110]}$ Another metric that can be calculated is the percent of buried volume of a ligand in a transition metal complex, which can be described as the amount of space occupied by a ligand inside a sphere of a predefined radius ( $3.5 \AA$ for this work) centered on the metal atom. This can be useful for the determination of catalytic pockets and the generation of space mapping for ligands. [111][112]

### 1.5 Applications of Organic Superbases

Organic superbases can be utilized in a variety of ways. In this section we will examine a host of examples that can be categorized broadly in stochiometric transformations, where the base is employed in a quantity of at least 1.0 equivalents as a base or a nucleophile (Section 1.5.1), catalytic transformations, where the base is employed in substochiometric quantities (Section 1.5.2) and applications where the base is employed as a ligand for transition metal catalyzed reactions (Section 1.5.3) ed

### 1.5.1 Stochiometric Transformations

Phosphazene bases have been utilized in stochiometric application for the synthesis of Cannelated pyrroles from unreactive nitroquinolines (Scheme 1.15). The usage of a phosphazene base was imperative for these transformations, as DBU did not yield the desired product. This is achieved by deprotonation of an isocyanoacetate ester, which attacks the nitroarene. Intramolecular nucleophilic attacks on the terminal carbon of the isocyano group generates the five membered ring. Through 1,2 -elimination of the nitro group, the product is generated. [114]

Scheme 1.15: Alkylation of 6-nitroquinoline with ethyl isocyanoacetate. [114]

They are also able to couple aryl iodides with thiophenols with a catalytic amount of CuBr in an Ullmann coupling to biarylthioethers (Scheme 1.16). The generation of a 'naked' thiol anion by deprotonation is a key step in this transformation. While DBU was also used successfully for these transformations it did perform worse, while other bases such as triethylamine and $N, N$-dimethylaminopyridine did not produce the desired product. Aryl

[^3]chlorides did not react, and aryl bromides were only able to couple while bearing electron withdrawing groups on the aryl core. [42]

Scheme 1.16: Nucleophilic aromatic substitution reaction between 1-iodo-4-methoxybenzene and 4-chlorobenzenethiol. [42]

Amidines like DBU as well as guanidines like MTBD can be utilized for the base promoted addition of chloroform to benzaldehyde (Scheme1.17). It can be applied to a range of aromatic and aliphatic aldehydes and ketones, but large aldehydes like mesitylaldehyde may hinder the reaction. ${ }^{[115]}$

Scheme 1.17: Base promoted addition of chloroform to benzaldehyde. 115

Schwesinger's $\mathrm{P}_{4}-t \mathrm{Bu}$ base allows for the JULIA-Kocienski olefination reaction in one pot between alkyl 3,5-bis(trifluoromethyl)phenylsulfones and aldehydes with excellent stereoselectivities (Scheme 1.18). It surpasses the performance of traditional bases like KHMDS and KOH in both yield and selectivity. [116]

Scheme 1.18: JULIA-KOCIENSKI olefination reaction between 1-(benzylsulfonyl)-3,5bis(trifluoromethyl)benzene and benzaldehyde. [116]

Dielmann et al. recently published a one pot method for the degradation of $\mathrm{SF}_{6}$ into nonvolatile solids by reaction with a superbasic IAP (Scheme 1.19, top). Depending on the basicity of the utilized IAP, either an ionic IAP $-\mathrm{SF}_{5}$ salt or complete degradation into a mixture of phosphine sulfides and difluorophosphines is reported. [117] Shibata et al. were able to utilize SCHWESINGER's $\mathrm{P}_{4}-t \mathrm{Bu}$ base to deprotonate fluoroform $\left(\mathrm{CHF}_{3}\right)$ and react the resulting trifluoromethyl anion with carbonyl compounds (Scheme 1.19, bottom). ${ }^{43]}$ This is accomplished through the highly active 'naked' $\mathrm{CF}_{3}$ anion that is generated by deprotonation. Weaker bases like DBU, TMG and $\mathrm{P}_{1}-t \mathrm{Bu}$ were not strong enough for this transformation.

Scheme 1.19: Synthesis of superbasic IAP and subsequent degradation of $\mathrm{SF}_{6}{ }^{[117]}$ (top) and $\mathrm{P}_{4}-t \mathrm{Bu}$ mediated trifluoromethylation of 2-naphthaldehyde (bottom). [43]

### 1.5.2 Organocatalytic Applications

Catalytically, Schwesinger's phosphazene bases have been employed in a number of transformations. For example, a nucleophilic substitution reaction between difluoroalkenes and ketene silyl acetals has been performed with excellent yields and selectivities.[118] (Scheme [1.20, top) With catalytic loads of $10 \mathrm{~mol} \%$, it outperformed both TBAF as well as Verkade's proazaphosphatrane bases. The functionalization of aryltrimethylsilanes with aldehydes with the use of $\mathrm{P}_{4}-t \mathrm{Bu}$ has also been reported (Scheme [1.20, middle). ${ }^{[119]}$ It is interesting to note, that weaker bases like DBU and $\mathrm{P}_{2}-t \mathrm{Bu}$ did not show any conversion, suggesting that the extreme basicity of $\mathrm{P}_{4}-t \mathrm{Bu}$ is imperative for this reaction. The superbase acts as a nucleophile in this reaction by abstracting the TMS group. BAE et al. published a thia-Michael addition of alkenyl sulfonyl fluorides with thiols catalyzed by $\mathrm{P}_{4}-t \mathrm{Bu}$ with an impressive catalyst loading of only 0.01 to $0.5 \mathrm{~mol} \%$ (Scheme [1.20, bottom). ${ }^{[120]}$ The authors state, that the reaction shows almost no reactivity in organic solvents such as THF, but by utilizing a mixture of THF and brine the yield is increased to almost quantitative quantities. They attribute this to hydrophobic hydration of the components, where the reaction takes place in a hydrophobic pocket surrounded by a highly polar aqueous $\mathrm{H}_{2} \mathrm{O} \cdot \mathrm{NaCl}$ sphere. [121|[122]

Scheme 1.20: Nucleophilic substitution of difluoroalkenes with ketene silyl acetals (top), [118] desilylation reaction of aryltrimethylsilanes with aldehydes (middle) 119 and thia-michael addition of alkenyl sulfonyl fluorides with phenylmethanthiol. ${ }^{120]}$ (bottom)

Terada et al. reports the Aza-Henry reaction of ketimines using guanidine as well as phosphazene bases (Scheme 1.21 top). The addition of nitromethane to $N$-phosphinoyl ketimines is achieved by addition of $10 \mathrm{~mol} \%$ of base. They report, that TMG, $\mathrm{P}_{1}-t \mathrm{Bu}$ as well as MTBD achieve good results. ${ }^{[123]}$ Pollini et al. report the addition of primary nitroalkanes to aldehydes and ketones with the help of catalytic amounts of TMG (Scheme [1.21, middle). ${ }^{[124]}$ They also reported the TMG catalyzed addition of dialkylphosphites to alkenenitriles, aldehydes and ketones (Scheme 1.21 bottom). These phosphonates can be used as intermediates for their application in the Wadsworth-Emmons reaction. [125]

86\%
Scheme 1.21: Aza-Henry reaction of ketimines (top) ${ }^{[123]}$, reaction of nitromethane with aldehydes (middle) ${ }^{[124]}$ and addition of nitromethane to diethylphosphite (bottom). ${ }^{[125]}$

VERKADE reports the base catalyzed reaction of aldehydes with allyltrimethylsilanes to yield homoallylic alcohols (Scheme [1.22, top). ${ }^{[126]}$ They suggest, that the reaction proceeds by coordination of the base with allyltrimethylsilane to form an anionic allyl and Base-TMS. An attack on the carbonyl yields an anionic allylalcohol which in turn attacks the TMS group located on the base, regenerating it. A subsequent aqueous workup liberates the desired allyl alcohol. Similarly, they report the trimethylsilylcyanation of aldehydes with $10 \mathrm{~mol} \%$ of base which proceeds similarly. ${ }^{[127]}$ First abstraction of the TMS group onto the base and generation of an anionic species and subsequent attack on the carbonyl compound (Scheme 1.22, bottom).

Scheme 1.22: Reaction of proazaphosphatrane catalyzed reaction of allyltrimethylsilane with benzaldehyde (top) ${ }^{[126]}$ and reaction of trimethylsilylcyanide with benzaldehyde (bottom). 127]

### 1.5.3 Applications as Ligands for Transition Metal Catalysis

Another field of applications for superbasic compounds, especially for phosphines and carbenes, is their usage as ligands for transition metal catalysis. VERKADE reported the usage of their proazaphosphatrane phosphines in palladium catalyzed C-C and C-N coupling reactions (Scheme [1.23, top). [79] They report the coupling of aryl bromides and chlorides with arylboronic acids with catalyst loads of $2 \mathrm{~mol} \%$ of palladium and $4 \mathrm{~mol} \%$ of ligand. They achieve good tolerances for a variety of functional groups like $\mathrm{OMe}, \mathrm{CF}_{3}, \mathrm{CN}$ and $\mathrm{NO}_{2}$. Similarly, they reported the palladium catalyzed BUCHWALD-HARTWIG amination reaction of aryl chlorides and bromides with secondary amines (Scheme 1.23 , bottom). ${ }^{80}$ They achieve good yields with catalyst loads as low as $0.25 \mathrm{~mol} \%$ for electron rich and neutral amines with both electron withdrawing as well as electron rich aryl halides.

Scheme 1.23: Palladium catalyzed cross coupling reactions with proazaphosphatrane phosphine ligands. ${ }^{[79 \mid 80]}$

Dielmann reports the usage of $\left[\mathrm{Au}(\mathrm{IAP}) \mathrm{BF}_{4}\right]$ complexes for the gold catalyzed hydroamination of acetylenes with anilines (Scheme 1.24). 128] They outperform BuchwALD-type ligands like JohnPhos with catalyst loads of $2 \mathrm{~mol} \%$. GESSNER reports the same reaction with ylide functionalized phosphines as ligands instead. ${ }^{[73]}$ They can be employed in extremely low catalyst loads of only 5 ppm and still achieve high yields of $72 \%$.

Scheme 1.24: Gold catalyzed hydroamination of phenylacetylene with aniline using YPhos ${ }^{[73]}$ $\left(\mathrm{L}_{1}\right)$ and IAP ${ }^{[128]}\left(\mathrm{L}_{2}\right)$ ligands.

## 2 Aim of this work

The aim of this thesis can be separated into three different topics. The first topic was to complement the series of already known trisphosphazenyl phosphines by lower substituted mono- and bisphosphazenyl phosphines, related to the work of UlLRICh. ${ }^{[86]}$ These new monoand bisPAPs were designed to be related to the famous ligand $\mathrm{P} t \mathrm{Bu}_{3}$. By substitution of one or two $t$-butyl groups with phosphazenyl groups, the electron donating capabilities of these ligands could be increased while their sterical and weak $\pi$-acceptor properties could be preserved (Scheme 2.1).

Scheme 2.1: Combination of electron rich phosphazenyl phosphines (bottom left) and bulky alkyl groups (top left) for new mono- and bisphosphazenyl phosphine hybrids.

In order to further the understanding of this class of compounds, the electronic, sterical and chemical properties should be investigated. The electronic character can be quantified by the Tolman parameter via the synthesis of a row of nickel tricarbonyl complexes and measurement of the $A_{1}$ vibrational mode of the carbonyl bond. Further insight can be gained by the synthesis of PAP selenides and the measurement of the phosphorus selenium coupling constant ${ }^{1} J_{(P, S e)}$. Additionally, the solution basicity should be determined by measurement of a competition experiment of a base of known $\mathrm{p} K_{B H^{+}}$value. Through quantitative ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy and integration of the product peaks the basicity can be determined by the ratio of protonated species To support these findings, DFT calculations of the solution and gas phase basicity as well as proton affinity should be performed. Additionally, the donor properties were supposed to be calculated by analyzing the change in Mulliken charges of the ligands upon addition of a nickel tricarbonyl fragment. Sterical parameters like the exact cone angle and the solid angle can be calculated from both XRD and DFT optimized structures, as well as the buried volume of the ligand sphere. This allows for the prediction of the behavior of these ligands upon coordination to substrates for catalytic applications. The chemical properties can be investigated by the execution of stability tests upon hydrolysis

[^4]in acidic, basic and neutral media. The nucleophilicity can be measured by reaction of a base with ethyl iodide and the determination of the ratio of protonated to alkylated base by quantitative ${ }^{31} \mathrm{P}$-NMR spectroscopy. Additionally, $\mathrm{CO}_{2}$ adducts as well as a number of metal complexes were supposed to be synthesized in order to investigate the reactivities of the PAPs (Scheme 2.2).

Scheme 2.2: Reactions to determine the electronic, steric and chemical properties of novel mono- and bis PAPs.

The second topic of this thesis was the application of trisPAPs and newly synthesized monoand bisPAPs as ligands in transition metal catalysis. Similar ligands such as IAPs, YPhos, Verkade or the Fu catalyst can be utilized in palladium catalyzed cross coupling reactions, so the application opportunities of PAPs in these reactions was of great interest. [59|79 [1290|130] They should be tested for Suzuki-Miyaura, Buchwald-Hartwig aminations, Kumada and Negishi couplings as well as nickel catalyzed Suzuki-Miyaura and Buchwald-Hartwig couplings (Scheme [2.3). Additionally, gold catalyzed aminations of acetylenes should be attempted.

& R^{2}=\text { aryl, alkyl }
\end{aligned}
$$

$$
\begin{aligned}
& \mathrm{R}^{\prime}=+\mathrm{R}^{\prime \prime}-\mathrm{NH}_{2} \xrightarrow{\mathrm{PAP}-\mathrm{AuCl}} \overbrace{\mathrm{R}^{\prime}}^{\mathrm{N}^{-\mathrm{R}^{\prime \prime}}}
\end{aligned}
$$

Scheme 2.3: Proposed metal catalyzed cross coupling reactions with PAP ligands.

The third area of interest for these newly synthesized PAPs were supposed to be organocatalytic applications. Spurred by the discovery of the ability of trisPAPs to deprotonate
acetonitrile, the catalytic applications of this reaction should be explored by the transfer of a $-\mathrm{CH}_{2} \mathrm{CN}$ group to carbonyl compounds. Related to this is the catalytic alkylation of indoles that can be performed by other strong metal containing bases such as $\mathrm{KO} t \mathrm{Bu}$ and cyclopropenimine superbases. ${ }^{[131-[133]}$ The addition of $\mathrm{CO}_{2}$ to epoxides is known to be catalyzed by NHCs, leading to cyclic carbonates. ${ }^{[134[135]}$ The question if this principle can be applied to superbasic PAPs was another task that was supposed to be investigated (Scheme 2.4).

Scheme 2.4: Proposed organocatalytic transformations of PAP catalysts.

## 3 Synthesis and Characterization of Phosphazenyl Phosphines

### 3.1 Results and Discussion

Trisphosphazenyl phosphines are the to date strongest P-bases known in chemistry, demonstrating an even higher proton affinity, gas phase and solution basicity than the corresponding polyphosphazene $N$-bases containing the same number of phosphorus atoms. ${ }^{[85]}$ Relatively little is known of the easier accessible mono- and bisPAP
$\left(\mathrm{R}_{\mathrm{x}} \mathrm{P}\left(\mathrm{N}=\mathrm{PR}^{\prime}{ }_{2} \mathrm{R}{ }^{\prime}\right)_{y} ; x, y \neq 0, x+y=3\right) .{ }^{[85[86]}$ SchmidBaUR et al. reported the synthesis of the simplest monoPAP from the reaction of TMS- $\mathrm{NPMe}_{3}$ and $\mathrm{MePCl}_{2}$ and the synthesis of the corresponding bisPAP from TMS-NPMe $3_{3}$ and $\mathrm{Me}_{2} \mathrm{PCl}$. ${ }^{[136]}$ Flindt reports the synthesis of a monoPAP from TMS-NPMe 3 and a phosphinic ester $\left(\mathrm{Ph}_{2} \mathrm{P}-\mathrm{OCH}_{2} \mathrm{CF}_{3}\right)$ (Scheme [3.1). ${ }^{[137]}$ Other representatives of this substance class are phosphazenyl phosphines based on VERKADE's proazaphosphatrane cage, as already mentioned in the introduction. [790[80]

Scheme 3.1: Known synthesis of mono- and bisPAP.

Based upon this, a range of target ligands was developed that would allow the systematic exploration of the electronic and sterical parameters of this substance class. The evaluation of the chemical behavior was another goal that should lead to the utilization of this substance class in a number of transformations. The target ligands are displayed in Figure 3.1. A manuscript describing most of the results herein has been prepared, but has as yet not been submitted. The synthesis and characterization of $\mathbf{5 e}$ and $\mathbf{5 f}$ has been published. ${ }^{[138]}$

$5 \mathbf{a}$

5 b

Figure 3.1: Overview over the target ligands for this work.

### 3.1.1 Synthesis of monoPAP 5a to $5 f$ and 9

To synthesize $\mathbf{5 a}$ to, $\mathbf{5 f}$ a strategy starting from a $\mathrm{P}($ III $)$-amide or a tertiary phosphine by Staudinger reaction with $\mathrm{TMSN}_{3}$ was chosen. The reaction proceeds by nucleophilic attack of the phosphorus lone pair onto the azide (a) (Scheme 3.2). The negatively charged terminal nitrogen atom then attacks the central phosphorus atom (b) by formation of a four membered triazaphosphete ring (c). Through elimination of molecular nitrogen, the products 3a to 3d are formed (d). ${ }^{[39]}$

Scheme 3.2: StaUdinger reaction between TMS azide and a tertiary phosphine.

These are subsequently reacted with $\mathrm{PCl}_{3}$ to form monophosphazenyl phosphorus dichlorides 4a to $\mathbf{4 d}$ through elimination of TMSCl. These phosphorus dichlorides are alkylated by $t$-BuLi to form the final target ligands $\mathbf{5 a}$ to $\mathbf{5 d}$ in excellent yields. The all amine substituted monoPAPs $\mathbf{5 e}$ and $\mathbf{5 f}$ are synthesized by reaction of the monophosphazenyl phosphorus dichlorides with gaseous dimethylamine or potassium pyrrolidide and subsequent distillation (Scheme [3.3). [138]

Scheme 3.3: Performed synthetic route towards monoPAPs 5a to $\mathbf{5 f}$.

This described synthetic strategy allows the introduction of other sterically demanding groups at intermediates $\mathbf{4 a}$ to $\mathbf{4 d}$, although tert-butyl groups have proven to be the most selective. The choice of $\mathrm{Et}_{2} \mathrm{O}$ as the solvent turned out to be essential. The lattice energy of precipitating LiCl is an essential driving force in order to obtain LiCl free pure superbasic monoPAPs. In THF, even at low temperatures, a significant amount of side products were formed, most likely through some type of radical WURTZ reactions or ether cleavage. Additionally, it turned out that a much better conversion could be achieved, if the lithium organyl was added to the phosphorus dichloride and not vice versa. The speed of this addition was also a factor, as a slow addition proved superior. If these factors are considered, the conversion is highly selective and can easily be tracked by ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy, as seen in Figure 3.2 for the transformation of $\mathbf{1 a}$ to $\mathbf{5 a}$. 5 a to $\mathbf{5 d}$ are white solids that are soluble in pentane, THF and toluene while possessing limited solubility in MeCN and DMSO. Single crystals suitable for $X$-Ray analysis were obtained by dissolving monoPAPs in DMSO at $150^{\circ} \mathrm{C}$ and slowly cooling to room temperature. 5 e and $\mathbf{5 f}$ are viscous oils at room temperature. ${ }^{[138]}$ They are all air and moisture sensitive and should be stored in a glovebox.

Figure 3.2: ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(121 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ spectra of the transformation from $\mathbf{1 a}$ to $\mathbf{5 a}$.

As seen in Figure 3.2 the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ signal of $\mathbf{1 a}$ shifts from 122.8 ppm to 14.7 ppm in $\mathbf{3 a}$ through StaUdinger reaction with TMS azide. After reaction with $\mathrm{PCl}_{3}$ two phosphorus signals can be detected as expected. The new doublet at 146.5 ppm corresponds to the trivalent phosphorus atom of $\mathbf{4 a}$ with two chloride substituents. Alkylation shifts this signal to 85.4 ppm with a coupling constant of 100.5 Hz . monoPAPs $5 \mathbf{a}$ to $5 \mathbf{f}$ all exhibit similar chemical shifts. It is noteworthy, that the coupling constant for alkyl substituted $5 \mathbf{5}$ and $\mathbf{5 d}$ is significantly lower than that of their amine substituted analogues with 57.3 Hz and 26.7 Hz respectively. It is likely that this decrease is at least partially attributed to a decrease of the electronegativity of the substitutents on the phosphazene core. [140[141] monoPAP 9 was designed to act as an $\pi$-acceptor in addition to being a $\sigma$-donor, in contrast to the overwhelming $\sigma$-donors $\mathbf{5 a}$ to $\mathbf{5 f}$. For this synthesis a different approach was needed, it consisted of the reaction of a chlorophosphite $\mathbf{8}$ with $N$-lithiated iminophosphorane $\mathbf{2 a} \mathbf{a} \mathbf{L i}$. ${ }^{142}$ 8 is readily available by reaction of 2,6 -diisopropylphenol (dippOH) with $\mathrm{PCl}_{3}$ and a catalytic amount of NMP (Scheme 3.4). 143]

Scheme 3.4: Synthesis of monoPAP 9 from 8 and $\mathrm{PCl}_{3}$.

The reaction can be observed by ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy through the shift of the signal of 8 from 174.3 ppm to 150.2 ppm . A new signal at 24.5 ppm corresponds to the pentavalent phosphorus center with a coupling constant of 64.5 Hz , which is significantly lower than 5a which possesses the same phosphazene core (Figure 3.3). This can be attributed to the increased steric hindrance of this PAP induced by the added dipp groups. The chemical shift of the trivalent phosphorus center is notable compared to $5 \mathbf{a}$, this is due to lower electron density induced by -Odipp which causes a lower shielding of the nucleus resulting in a downfield shift. 9 is a white solid that is sensitive to air and moisture. Single crystals suitable for XRD were obtained in the already described way.

Figure 3.3: ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(121 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ spectra of the reaction from $\mathbf{8}$ to $\mathbf{9}$.

### 3.1.2 Synthesis of bisPAP 6a, 6b and 13

To complete the series of alkyl-substituted PAP, bisPAPs $\mathbf{6 a}$ and $\mathbf{6} \mathbf{b}$ were synthesized. For this a new strategy had to be employed because the theoretical intermediate
$\mathrm{Cl}-\mathrm{P}\left(\mathrm{N}=\mathrm{PR}_{3}\right)_{2}$ is known to be unstable and prone to decomposition. ${ }^{[144]}$ Instead, alkyl- $\mathrm{PCl}_{2}$ compounds were reacted with lithiated iminophosphoranes. The lithiation of iminophosphoranes proceeds in quantitative yields at low temperatures in $\mathrm{Et}_{2} \mathrm{O}$. By careful addition of alkyl- $-\mathrm{PCl}_{2}$, the desired bisPAPs could be generated (Scheme 3.5). Again, the rate and order of addition is important, as a too fast addition leads to the generation of side products, specifically Cl-P $(t \mathrm{Bu})\left(\mathrm{N}=\mathrm{PR}_{3}\right)$ as evident by ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy.

Scheme 3.5: Used synthetic route towards bisPAPs $\mathbf{6 a}$ and $\mathbf{6 b}$.

When comparing the ${ }^{31} \mathrm{P}$-NMR spectra of monoPAP, bisPAP and trisPAP a clear trend is visible in the chemical shifts of the pentavalent phosphorus atoms as evident by Figure 3.4. The signal shifts upfield for each added phosphazenyl group, from $31.4 \mathrm{ppm}(\mathbf{5 a})$ to 20.4 ppm (6a) to $14.4 \mathrm{ppm}(\mathbf{7 a})$. A similar trend can be observed when comparing the ${ }^{2} J_{(P, P)}$ coupling constants. Each added phosphazenyl group decreases the coupling constants from 100.5 Hz (5a) to $59.3 \mathrm{~Hz}(\mathbf{6 a})$ to $19.6 \mathrm{~Hz}(\mathbf{7 a})$. $\mathbf{6 a}$ is a viscous liquid, while $\mathbf{6 b}$ is a white solid. Both compounds are extremely air and moisture sensitive and should be stored in a glovebox. They are soluble in apolar solvents such as pentane, as well as more polar solvents like THF. Single crystals of $\mathbf{6} \mathbf{b}$ could be obtained in the same matter as its monoPAP analogues, while even at $-30{ }^{\circ} \mathrm{C}$ no crystals could be obtained for $\mathbf{6 a}$. Their structural parameters will be discussed in a later section. In order to diversify this class of ligands another target, 13, was designed with a biaryl backbone that resembles the famous Buchwald ligands commonly used in transition metal catalyzed cross couplings. ${ }^{[84]}$ This biaryl backbone may undergo $\pi$-arene interactions that stabilize the intermediate after oxidative addition of a substrate. The starting point for this synthesis was 2 -bromo- $3^{\prime}, 5^{\prime}$ '-dimethoxy-1,1'-biphenyl, which would allow further functionalization on the 2 position of the biaryl moiety. It was synthesized according to literature procedures by a Suzuki-MiYaura cross coupling reaction. ${ }^{[145]}$ The next step involved a bromine-lithium exchange reaction at low temperatures with $n$ - BuLi and a subsequent trapping step with $\mathrm{Cl}-\mathrm{P}\left(\mathrm{NEt}_{2}\right)_{2}$. A direct reaction of $\mathrm{PCl}_{3}$ with this lithiated biaryl led to the generation of a variety of side products, and therefore this protecting group strategy was employed. Subsequent reaction of $\mathbf{1 1}$ with HCl in dioxane, which cleaved the diethylamino groups, liberated the aryl- $\mathrm{PCl}_{2}$ compound 12. 12 was recrystallized from a mixture of toluene and $\mathrm{Et}_{2} \mathrm{O}$ and stored at $-30{ }^{\circ} \mathrm{C}$ as it decomposed at room temperature over time even under inert atmosphere. Afterward, reaction with 2a-Li yielded target ligand 13 (Scheme (3.6).

Figure 3.4: ${ }^{31} \mathrm{P}$-NMR shift and ${ }^{2} J_{(P, P)}$ coupling constants of the pentavalent phosphorus atoms of $\mathbf{5 a}$ (bottom), $\mathbf{6 a}$ (middle) and $\mathbf{7 a}$ (top).

Scheme 3.6: Employed synthetic route to 13.

This reaction was extremely sensitive to temperature and addition rate, as reported before for $\mathbf{6 a}$ and $\mathbf{6 b}$. 13 could not be obtained free of contaminants, mainly $\mathbf{2 a}$, which inhibited further applications such as the measurement of its basicity (see Section 3.1.4).

Another target ligand 18 was designed to possess multiple coordination sites for metals and to provide $\pi$-arene interactions with possible substrates. The synthesis is based upon the reaction of $\mathrm{AlCl}_{3}, \mathrm{PCl}_{3}$ and $\mathrm{CCl}_{4}$ to generate $\mathbf{1 4}$ according to a literature procedure. [146] Through reaction with gaseous diethylamine under abstraction of diethylammonium chloride 15 is generated. ${ }^{[147]}$ Subsequent reaction with gaseous ammonia yields the free iminophosphorane 16. ${ }^{[148]}$ Through elimination of $\mathrm{CHCl}_{3}, 16$ reacted with phenol to yield 17 . ${ }^{[149]} \mathrm{A}$ subsequent reaction with $n$-BuLi yielded the lithiated iminophosphorane $17-\mathrm{Li}$, which would react with $t-\mathrm{BuPCl}_{2}$ to form the target ligand 18. However, only mono-substituted product $\left(\mathrm{R}_{3} \mathrm{P}=\mathrm{NP}(t \mathrm{Bu}) \mathrm{Cl}, 19\right)$ could be isolated. Therefore, it was decided if it would be possible to first, generate the bis-substituted chlorophosphine and afterward react this compound with $t$-BuLi to yield the target ligand. The first reaction did prove successful, however the subsequent alkylation with $t$-BuLi did not proceed. The whole reaction sequence is displayed in Scheme 3.7 .

Scheme 3.7: Attempted synthesis for target ligand 18.

An overview over the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ chemical shifts and the ${ }^{2} J_{(P, P)}$ coupling constants of all synthesized PAPs in this chapter is shown in Table 3.1 .

Table 3.1: Overview over the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ chemical shifts and the ${ }^{2} J_{(P, P)}$ coupling constants of PAP.

| MonoPAP | $\mathbf{5 a}$ | $\mathbf{5 b}$ | $\mathbf{5 c}$ | $\mathbf{5 d}$ | $\mathbf{9}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |

### 3.1.3 Structural Features of PAP

Single crystals of monoPAPs $\mathbf{5 a}$ to $\mathbf{5 d}$ (Figure 3.5) as well as phosphoramidite $\mathbf{9}$ and bisPAPs $6 \mathbf{b}$ (Figure 3.6) could be obtained by dissolving the corresponding PAP in DMSO at $150{ }^{\circ} \mathrm{C}$. Slowly cooling to RT yielded crystals suitable for X-Ray diffraction MonoPAPs 5a to 5c contain P1-N1 distances that lie between $1.67 \AA(\mathbf{5 c})$ and $1.68 \AA(\mathbf{5 a})$. This is shorter than the reported bond lengths for $\mathrm{P}(\mathrm{tmg})_{3}(1.70 \AA)$. 82 ]

Figure 3.5: Molecular structure of 5a (top, left), 5b (top, right), 5c (bottom, left) and 5d (bottom, right). Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles [ ${ }^{\circ}$ ]: 5a: C11-P1 1.89(3), N1-P1 1.68(2), N1-P2 1.55(2), N4-P2 1.65(2), P2-N1-P1 125.0(1), N1-P1-C11 101.0(1), N1-P2-N2 121.8(1). 5b: N1-P1 1.68(2), N1-P2 1.57(2), C5-P1 1.90(3), P2-N1-P1 126.8(1), 126.8(1) N1-P2-N4 121.6(1). 5c: N1-P1 1.67(2), C5-P1 1.91(2), C9-P2 1.83(2), N1-P2 1.56(2), P2-N1-P1 137.9(1), N1-P1-C5 101.3(1). 5d: P1-C1 1.92(1), N1-P1 1.68(1), N1-P2 1.57(1) 1.57(1), P2-N1-P1 143.3(7), N1-P1-C5 103.0(6), N1-P2-C13 109.6(6).

[^5]This can be attributed to a lower contribution of negative hyperconjugation as evidenced by its inherent lower basicity. The P2-N1 bond lengths are between $1.55 \AA$ (5a) and $1.59 \AA$ (5b) and are characteristic for $\mathrm{P}(\mathrm{V})=\mathrm{N}$ formal double bonds strengthened via negative hyperconjugation. ${ }^{[150 \mid 151]}$ The P1-N1-P2 bond angles are between $125^{\circ}$ and $143^{\circ}$, with the bulkier 5c and $\mathbf{5 d}$ at the higher end of this spectrum. This can be attributed to increased steric demand of the cyclohexyl and $t$-butyl groups. The crystals of $\mathbf{5 a}$ and $\mathbf{5 b}$ are in the same range as the trisPAPs ( $\mathbf{7 a}$ and $\mathbf{7 b}$ ) while $\mathbf{5 c}$ and 5 d are much higher. For monoPAP 9 the P1-N1 bond length of $1.62 \AA$ is shorter than in monoPAPs 5 a to $5 \mathbf{d}$. The N1-P2 bond length is $1.57 \AA$ and therefore comparable to usual P-N double bonds. The P1-N1-P2 bond angle of $\mathbf{9}$ is $133.4^{\circ}$ and is therefore on the higher end of the spectrum because of the bulky dipp groups. P1-O1 and P1-O2 bond lengths average $1.68 \AA$ and are comparable to typical P-O single bonds. BisPAP 6 b features P1-N1 and P1-N5 bond lengths of $1.66 \AA$ and $1.69 \AA$ respectively and are very similar to its monoPAP analogues. The bond angle of P2-N1-N1 is comparable to bulky 5 d with $141.7^{\circ}$.

Figure 3.6: Molecular structure of 9 (left) and 6b (right). Ellipsoids are set at $50 \%$ probability. Hydrogens are omitted for clarity. Notable bond lengths $[\AA]$ and angles ${ }^{[ }{ }^{\circ}$ : 9: N1-P1 1.62(4), N1-P2 1.57(3), O1-P1 1.69(3), O2-P1 1.68(3), C19-O2-P1 125.3(2), N1-P1-O1 100.7(2), P2-N1-P1 133.4(2). 6b: N5-P3 1.58(6), N5-P1 1.69(6), N1-P1 1.66(6), C1-P1 1.89(6), N1-P2 1.54(6), N5-P3-N6 123.8(4), P2-N1-P1-141.7(4).

Single crystals of iminophosphorane hydrochloride salt $\mathbf{1 7}-\mathrm{HCl}$ could be obtained by decomposition of the free iminophosphorane in $\mathrm{Et}_{2} \mathrm{O}$. The hydrochloride possesses a P1-N3 bond length of $1.61 \AA$ which is comparable to $\left[\left(\mathrm{NMe}_{2}\right)_{3} \mathrm{P}=\mathrm{NH}_{2}\right]^{+}$and a P1-N1 bond length of $1.62(2) \AA$ which is slightly shorter than $\left[\left(\mathrm{NMe}_{2}\right)_{3} \mathrm{P}=\mathrm{NH}_{2}\right]^{+}$with $1.63(2) \AA$. ${ }^{[86]}$ The P1-O1 bond length of $1.56 \AA$ is shorter than that of $\mathrm{P}(\mathrm{O})\left(\mathrm{NH}_{2}\right)_{2} \mathrm{OPh}(1.59 \AA)$. ${ }^{[152]}$ The bond angles around P 1 suggest a slightly disordered tetrahedral structure, as is expected. Although it could not be synthesized, the structure of 18 in the gas phase was calculated utilizing the PBE functional with a basis set of def2/tzvpp in order to obtain an idea of the molecular structure (Figure [3.7). [153] [154]

Figure 3.7: Molecular structure of $17-\mathrm{HCl}$ (left) and calculated structure of 18 (right). Ellipsoids are set at $50 \%$ probability. Structure was calculated with PBE def2/tzvpp. ${ }^{[53][54]}$ Hydrogens are omitted for clarity except for those located on the terminal $\mathrm{NH}_{2}$ group. Notable bond lengths $[\AA]$ and angles [ ${ }^{\circ}$ : $17-\mathrm{HCl}: \mathrm{P} 1-\mathrm{N} 1$ 1.62(2), P1-O1 1.58(2), P1-N3 1.61(2), N3-P1-N1 117.3(1), O1-P1-N3 108.8(9), N2-P1-N1 111.6(9).

### 3.1.4 Evaluation of the Nucleophilicity

In order to evaluate the nucleophilicity of these new PAP ligands, they were reacted with an excess of dried ethyl iodide. There are two possible mechanisms for this reaction, either the PAP reacts as a nucleophile and forms a P-ethylated phosphonium PAP via $S_{N} 2$ reaction or the PAP reacts as a base in a $E_{2}$ reaction and is protonated (Scheme 3.8).

Scheme 3.8: Evaluation of the nucleophilicity of different PAP by reaction with EtI.

The ratio of products was determined by quantitative ${ }^{31} \mathrm{P}-\mathrm{NMR}$ measurement by inverse gated decoupling method with an increased relaxation delay (in relation to standard ${ }^{31} \mathrm{P}$ measurement) in order to guarantee complete relaxation between pulses. Therefore, the ratio of $\mathrm{PAP}-\mathrm{Et}^{+}$to $\mathrm{PAP}-\mathrm{H}^{+}$could be determined by the integration of the corresponding $\mathrm{P}(\mathrm{III})$ or $\mathrm{P}(\mathrm{V})$ signals. The results of these experiments can be seen in Table 3.2.

Table 3.2: ${ }^{31} \mathrm{P}-\mathrm{NMR}$ chemical shifts of $\mathrm{PAP}-\mathrm{Et}^{+}$to $\mathrm{PAP}-\mathrm{H}^{+}$and their ratio.

| Nucleophilicity [\%] ${ }^{\text {[b] }}$ | 45.4 | $1.0^{\text {e] }}$ | $\mathrm{n} / \mathrm{a}$ | 83.0 | 88.0 |

${ }^{\text {a }} \mathrm{P}^{\mathrm{III}} ; \mathrm{P}^{\mathrm{V}}$, measured in $\mathrm{MeCN}-\mathrm{d}_{3}$.
${ }^{\mathrm{b}}$ Ratio of the integrals of PAP-Et/PAP- $\mathrm{H}^{+}$.
${ }^{\text {c }}$ Only $27 \%$ reacted with EtI, of these $27 \%$ only $7 \%$ of PAP-Et was found.
${ }^{\mathrm{d}}$ Measured in $\mathrm{C}_{6} \mathrm{D}_{6}$ from $\mathrm{P}_{3} \mathrm{P} \cdot \mathrm{HBF}_{4}$ salt.
${ }^{e}$ Measured in THF- $\mathrm{d}_{8}$ due to low solubility of the isolated reaction mixture.

As expected, both protonation as well as alkylation induce a significant upfield shift of the formerly trivalent phosphorus nucleus: e.g., $\mathbf{5 a}$ to $\mathbf{5 a - H}, 85.4 \mathrm{ppm}$ to 46.0 ppm ; 5a to 5 a -Et 85.4 ppm to 42.5 ppm (Figure 3.8). The coupling constant also decreases drastically: 5a to 5a$\mathrm{H}, 100.5 \mathrm{~Hz}$ to $29.4 \mathrm{~Hz} ; 5 \mathbf{a}$ to $5 \mathbf{5}$-Et, 100.5 Hz to 3.7 Hz . In fact, the ${ }^{2} J_{(P, P)}$ coupling disappears completely for some P-ethylated PAPs. It is observed, that both trisPAPs $\mathbf{7 a}(83.0 \%)$ and $\mathbf{7 b}$ $(88.0 \%)$ react predominantly as C-nucleophiles, forming [PAP-Et] ${ }^{+}$. 86$]$ MonoPAPs $\mathbf{5 a}(60.9 \%)$ and $\mathbf{5 b}(51.7 \%)$ show a lower ratio towards ethylation. Interestingly, all PAPs with sterically demanding alkyl substituents ( $5 \mathbf{c}$ and $5 \mathbf{d}$ ) display predominantly the character of a base: only $12.0 \%$ ( $\mathbf{5 c}$ ) and $18.8 \% ~(5 d)$ of the $[\mathrm{PAP}-E t]^{+}$cations are formed next to $[\mathrm{PAP}-\mathrm{H}]^{+}$. This can be attributed to their difference in sterics as the alkyl core hinders an attack of the electrophile by the P(III) center. BisPAP 6a falls in between mono- and trisPAPs with $45.4 \%$. Surprisingly, sterically demanding bisPAP 6b presents as a pure base: When reacted under the same conditions as $\mathbf{6 a}$ in THF, only $1 \%[\mathrm{PAP}-\mathrm{Et}]^{+}$and $99 \%[\mathrm{PAP}-\mathrm{H}]^{+}$cations are formed. The high selectivity towards dehydrohalogenation is most likely due to steric hindrance introduced by the combination of P-pyrrolidino and P-tert-butyl groups. MonoPAP 9 is another example of high selectivity towards elimination by steric hindrance, as it is only ethylated by $7 \%$. It can be concluded, that PAP superbases have a considerable and competing P-nucleophilicity towards soft C-electrophiles such as alkyliodides. Bulky groups decrease their nucleophilic behavior and can, if introduced at the phosphazene core, even inhibit nucleophilicity. As nucleophilicity towards soft carbon electrophiles is qualitatively correlated to donor strength towards soft transition metal Lewis acids, PAP P-bases will display a different spectrum of applications compared to SCHWESINGER's N-bases.

Figure 3.8: ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(121 \mathrm{MHz}, \mathrm{MeCN}-\mathrm{d}_{3}\right)$ spectrum of 5 a before (bottom) and after (top) reaction with EtI.

### 3.1.5 Chemical Stability of PAP

The stability of PAPs towards hydrolysis in acidic and basic environments is of relevance because the phosphazene core can be hydrolyzed to form hexamethylphosphorous acid trisamide (HMPA) which is highly toxic and is known to cause cancer in rats. ${ }^{[155]-157]}$ In order to investigate this risk, three different reactions for each PAP were performed. PAP was dissolved in a small quantity of dioxane and subsequently 1 mL of a) 1 m HCl , b) 1 m NaOH or c) $\mathrm{H}_{2} \mathrm{O}$ was added and heated to reflux overnight. Afterward the solvent was removed, and the residue dissolved in $\mathrm{CHCl}_{3}$ and NMR spectra as well as MS measurements were taken. All synthesized PAP were stable under these conditions except for $\mathbf{5 c}$ which decomposed in acidic and basic media to form several phosphorus species, though none of them could be attributed to HMPA. In basic conditions, most monoPAPs reacted to form a mixture of protonated PAP $\left[\right.$ PAP-H] ${ }^{+}$and PAP oxides $[\mathrm{PAP}=\mathrm{O}]$ as detected by MS (Figure [3.9). In acidic media more
$[\mathrm{PAP}-\mathrm{H}]^{+}$is formed and in neutral media more $[\mathrm{PAP}=\mathrm{O}]$ is formed. Higher substituted bisPAPs ( $\mathbf{6 a}$ and $\mathbf{6 b}$ ) and trisPAPs ( $\mathbf{7 a}$ and $\mathbf{7 b}$ ) reacted almost exclusively to form $[\mathrm{PAP}-\mathrm{H}]^{+}$ no matter the media. All synthesized PAPs are thermally stable in DMSO at $150{ }^{\circ} \mathrm{C}$ with minimal decomposition. This method was used to grow single crystals for X-ray diffraction upon cooling of these saturated solutions. As already mentioned, all PAPs are sensitive towards water and oxygen and will eventually decompose into the corresponding PAP oxides or phosphonium salts. However, all these PAPs can be stored without decomposition even at humid conditions in form of their PAP- $\mathrm{HBF}_{4}$ salts, allowing storage of these compounds under ambient conditions. Deprotonation with a strong base such as KHMDS liberates the free bases for further use.

Figure 3.9: ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(121 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ spectrum of 5 a after reaction with $\mathrm{H}_{2} \mathrm{O}$ (bottom), HCl (middle) and NaOH (top).

### 3.1.6 Evaluation of the Tolman Electronic Parameter and PAP Selenides

To investigate the electronic properties of the ligands, the Tolman electronic parameter (TEP) was measured as mentioned in Section 1.4. The TEP corresponds to the frequency of the $A_{1} \mathrm{C}-\mathrm{O}$ vibrational mode of $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ type complexes. This can be used to determine the electron donor capabilities of a ligand. For this purpose each ligand was reacted with $\left[\mathrm{Ni}\left(\mathrm{CO}_{4}\right)\right]$, the resulting nickel complex was isolated and an IR spectrum of the solid compounds was measured. Additionally, the structure of each complex was calculated with DFT using the PBE functional and the def2/tzvpp basis set. ${ }^{[153][154]}$ PAP selenides allow a similar assumption about donor capabilities and have been prepared by reaction of each ligand with gray selenium. The synthesized and discussed compounds for this section are shown in Figure 3.9

31
Scheme 3.9: Overview over the synthesized and discussed molecules for this section.

An overview over the measured TEP is shown in Table 3.3. It can be deduced that monoPAPs $\mathbf{2 5 a}$ to $\mathbf{2 5 d}$ all possess TEPs of $2040 \pm 2$ which is lower (electron richer) than popular NHCs such as IMes $(2050.5)^{[158]}$ and $\operatorname{ImNMe}_{2}(2054.1)^{[158]}$ or phosphines like $\mathrm{P} t \mathrm{Bu}_{3}(2056.1)^{[9]}$ and to modern ylidenaminophosphines (IAP) ${ }^{[8] 159]}$ (Figure 3.10) of Dielmann and ylide functionalized phosphines (YPhos) ${ }^{[59[71 \mid 73]}$ of Gessner. Interestingly, they are also lower than all amino substituted analogues $\mathbf{2 5 e}(2047.4)$ and $\mathbf{2 5 f}(2042.4) .{ }^{[138]}$ This suggests, that alkyl substituents contribute more to the electron donating capabilities of a ligand than amino groups. 29, which shows a TEP of 2104.6, lies in the realm of $\mathrm{PF}_{3}$ which suggests, that it may compete with CO as an $\pi$-acceptor ligand. ${ }^{[90]}$ Unsurprisingly, 26a and 26b lie between monoPAPs 25a-25b and trisPAPs 27a-27b with TEP values of 2032.0 and 2033.5 respec-
tively. Biaryl PAP 31 fits in with these bisPAPs with a TEP value of 2036.7. With these values, they surpass even some of the strongest NHCs in donor capability. ${ }^{[85[158]}{ }^{13} \mathrm{C}$-NMR signals for these carbonyls can all be found around 200 ppm . The ${ }^{2} J_{(P, C)}$ constants increase for each added phosphazenyl unit from ca. 2.0 Hz for monoPAP, to 4.6 Hz for bisPAP to 9.0 Hz for trisPAP. Phosphoramidite 29 displays a singlett as its bulky dipp groups shield the phosphorus atom from coupling with the carbonyl units. A linear dependency between the calculated average bond lengths of the CO fragments of $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes could be correlated to their calculated $A_{1}$ C-O vibrational mode, as has been established by Gusev for a series of two electron ligands. ${ }^{[160]}$ This dependency was replicated for PAP as evident by Figure 3.11 with a $R^{2}$ value of 0.995 .

Table 3.3: Measured and calculated TEP, ${ }^{13} \mathrm{C}-\mathrm{NMR}$ chemical shifts and ${ }^{2} J_{(P, C)}$ of the carbonyl carbon of PAP and similar ligands.

[^6]

Figure 3.10: TEP values of the nickel tricarbonyl complexes of PAP and various other ligands. Exact values for these examples are given in Table 3.3,

Figure 3.11: Correlation of the average calculated CO bond lengths and $A_{1} \mathrm{C}-\mathrm{O}$ vibrational mode of $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes. Molecules numbered according to their parent PAP.

Single crystals suitable for XRD for 25a and 25d were obtained by slow cooling of a saturated pentane solution to $-30^{\circ} \mathrm{C}$. The structures are shown in Figure 3.12, 25a possesses an average C-O bond length of $1.15 \AA$ and $\mathbf{2 5 d}$ of $1.14 \AA$ which is, as expected, shorter than the average C-O bond length in 27a with $1.19 \AA$. ${ }^{86]}$ This corresponds to their lower TEP value as the $A_{1} \mathrm{C}-\mathrm{O}$ vibrational mode is harder to exite the shorter the bond length. The P1-Ni bond
lengths are similar with $2.298 \AA$ for $\mathbf{2 5 d}$ and $2.263 \AA$ for $\mathbf{2 5 a}$ compared to $2.259 \AA$ for $\mathbf{2 7 a}$. The higher bond length of $\mathbf{2 5 d}$ clearly stems from its increased sterical hindrance introduced by $t$-butyl groups on the phosphazenyl core.

Figure 3.12: Molecular structure of 25a (top) and 25d (bottom). Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles [ ${ }^{\circ}$ : 25a: N1-P1 1.628(5), N1-P2 1.531(5), N2-P2 1.642(5), N3-P2 1.654(5), N3-P2 1.654(5), P1-C4 1.894(6), P1-Ni1 2.2626(2), Ni1-C1 1.792(7), C1O1 1.148(8), O1-C1-Ni1 179.0(6), P2-N1-P1 161.3(4), C1-Ni1-P1 109.8(2), N1-P1-Ni1 116.8(2); 25d: N1-P1 1.644(2), N1-P2 1.563(2), P2-C12 1.899(2), P2-C16 1.897(2), P1-C4 1.917(2), P1-Ni1 2.298(6), Ni1-C1 1.797(3), C1-O1 1.136(3), O1-C1-Ni1 176.7(2), P2-N1-P1 159.2(1), C1-Ni1-P1 109.9(8), N1-P1-Ni1 120.7(7).

A similar evaluation of the donor capabilities can be made from the ${ }^{1} J_{(P, S e)}$ coupling constant of corresponding PAP selenides, their chemical shifts as well as their ${ }^{1} J_{(P, S e)}$ coupling constants are shown in Table [3.4] [102|107]

Table 3.4: ${ }^{31} \mathrm{P}$ and ${ }^{77}$ Se-NMR chemical shifts of PAP selenides and their ${ }^{1} J_{(P, S e)}$ coupling constants.

22a-22d all exhibit similar coupling constants of $694 \pm \mathrm{Hz}$. This is in the magnitude of 50 Hz lower than all amine substituted monoPAPs 22e and 22f. ${ }^{[138]}$ This difference can be attributed at least partly to the higher electron donor capabilities of 22a-22d as evidenced by their TEP values. Sterical hindrance at the central phosphorus atom may also result in a decrease in s-character of the lone pair. ${ }^{[103]}$ In the row of 22a, 23a to 24a a clear trend in the decreasing of the coupling constant by about 20 Hz per phosphazene unit can be observed. This corresponds with their TEP. This prompted an investigation to determine if a linear correlation between the TEP and the ${ }^{1} J_{(P, S e)}$ coupling constants is possible, as was shown by Gessner. ${ }^{[163]}$ Such a dependency was confirmed with a $R^{2}$ value of 0.987 (Figure 3.13, top). Notably, the fitted function was very similar to the one used by GESSNER with only a variance of $1 \pm 0.5 \%$ between our obtained values and values obtained by GESSNER's method. Phosphoramidite 28 presents a clear outlier to its electron rich monoPAP analogues, with a ${ }^{1} J_{(P, S e)}$ coupling constant of 902.2 Hz . This stems mostly from the electron withdrawing -Odipp groups, but bulky aryl substituents have been known to cause an increase in ${ }^{1} J_{(P, S e)}$ coupling constants that do not necessarily correlate to its electronic properties. 105[106] It can be said, that $\mathbf{9}$ is the ligand with the lowest donor and highest $\pi$-acceptor abilities within these PAPs. Betrand and Hudnall discovered a dependency of ${ }^{31} \mathrm{P}-\mathrm{NMR}$ and ${ }^{77} \mathrm{Se}-\mathrm{NMR}$ signals for phosphinidines and NHCs. ${ }^{[55][96]}$ This dependency extends to PAP as shown in Figure 3.13 (bottom) with a $R^{2}$ value of 0.962 .

Figure 3.13: Linear dependence of the ${ }^{1} J_{(P, S e)}$ NMR ( $57 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) coupling constant with the TEP (top). Linear dependence of the ${ }^{31} \mathrm{P}\left(121 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ and ${ }^{77} \mathrm{Se}-\mathrm{NMR}$ ( $57 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) chemical shifts of PAP selenides (bottom). Molecules numbered according to their parent PAP.

Single crystals suitable for XRD for 22a, 23b and $\mathbf{3 0}$ were obtained by slow cooling of a saturated pentane solution to $-30^{\circ} \mathrm{C}$. 22a features a P1-Se1 bond length of $2.140 \AA$ which is shorter than $\mathbf{2 3 b}$ with $2.156 \AA, \mathbf{3 0}$ with $2.163 \AA$ and $\mathbf{2 4 a} 2.167 \AA$. It can be concluded, that added phosphazenyl groups increase this bond length. The length is additionally increased by the sterically demanding biaryl substituent of $\mathbf{3 0}$. The second phenyl ring of $\mathbf{3 0}$ is twisted by $59.6^{\circ}$ in relation to the first phenyl ring. This may enable the parent ligand 13 to stabilize possible metal adducts via $\pi$-arene interactions, as shown by Buchwald's biaryl ligands. ${ }^{84]}$ The N1-P1-Se1 bond angles are between $112-115^{\circ}$, suggesting a slightly disordered tetrahedral coordination of P1. ${ }^{[86]}$

Figure 3.14: Molecular structure of 22a (left), 23b (right) and $\mathbf{3 0}$ (bottom). Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths [ $\AA$ ] and angles [ ${ }^{\circ}$ : 22a: Se1-P1 2.140(6), P1-N1 1.613(2), N1-P2 1.565(0), P2-N2 1.653(2), P1-C1 1.879(2), N1-P1-Se1 118.3(7), P1-N1-P2 137.3(1), N1-P2-N3 112.2(9); 23b: P1-Se1 2.156(5), P1-N1 1.623(2), N1-P2 1.553(2), P2N2 1.659(2), P1-C1 1.857(2), N1-P1-Se1 115.4(6), P1-N1-P2 142.2(1), N1-P2-N3 123.4(8); 30: P1-Se1 2.163(7), P1-N4 1.614(2), N4-P2 1.560(2), P1-C13 1.847(2), N4-P1-Se1 113.8(7), P1-N4-P2 137.3(1), N5-P3-N7 121.7(1), C13-C18-C19-C24 $-59.3(3)$.

Overall, it can be concluded that these measures are a reliable way to quantify the donor capabilities of PAP.

### 3.1.7 Experimental Determination of the Basicity

The basicity of PAP was determined experimentally as well as theoretically. Additionally, the gas phase basicity and proton affinity were calculated using DFT methods. Experimentally, the basicity could be determined by the competition reaction between a PAP and a reference base with a similar $\mathrm{p} K_{B H^{+}}$value by measurement of quantitative ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra as described in Section 3.1.4. An example for the determination of $\mathrm{p} K_{B H^{+}}$values is shown here:
$5 \mathrm{a}(8.57 \mathrm{mg}, 26.6 \mu \mathrm{~mol})$, MTBD ( $4.66 \mathrm{mg}, 30.4 \mu \mathrm{~mol}$ ) and bistriflimidic acid $\mathrm{HNTf}_{2}(5.78 \mathrm{mg}$, $26.6 \mu \mathrm{~mol}$ ) were dissolved in THF-d ${ }_{8}$, transferred to an NMR tube and shaken. The integrals of the resulting mixture of $\mathbf{5 a}$ and $5 \mathbf{a}-\mathrm{H}^{+}$were 0.67 and 0.33 (Figure 3.15). Therefore, the molarity of $5 \mathbf{a}$ and MTBD can be calculated as $17.7 \mu \mathrm{~mol}$ and $12.7 \mu \mathrm{~mol}$. The molarities of $5 \mathrm{a}-\mathrm{H}^{+}$and $\mathrm{MTBDH}{ }^{+}$are the differences of the starting molarity to the calculated molarity. The rate constant $K$ can now be calculated by equation 3.1 .

$$
\begin{equation*}
K=\frac{n\left[(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}\right] * n\left[\mathrm{MTBDH}^{+}\right]}{n[\mathrm{MTBD}] * n\left[(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2} \mathrm{H}^{+}\right]} \tag{3.1}
\end{equation*}
$$

The $\mathrm{p} K_{B H^{+}}$can be calculated by subtraction of the logarithm of $K$ with the $\mathrm{p} K_{B H^{+}}$of the reference base $\left(\mathrm{MTBD}=18.6\right.$ in THF). ${ }^{[23]}$

$$
\begin{equation*}
\mathrm{p} K_{B H^{+}}=18.6-\log (K)=18.6-\log 2.80=18.15 \tag{3.2}
\end{equation*}
$$

$\mathrm{p} K_{B H^{+}}$values of the THF scale (measured) can be correlated to the MeCN scale using correlation equation 3.3 reported by Leito et al. ${ }^{[23]}$

$$
\begin{equation*}
\mathrm{p} K_{B H^{+}}(T H F)=(0.92 \pm 0.02) * \mathrm{p} K_{B H^{+}}(M e C N)-(5.15 \pm 0.51)=24.8 \pm 0.1 \tag{3.3}
\end{equation*}
$$

These measurements were repeated for all PAPs except for $\mathbf{9}$ because its basicity proved to be lower than $\mathrm{NEt}_{3}$ and therefore wasn't pursued further. The measurements for $\mathbf{1 3}$ could not be taken, as impurities of $\mathbf{2 a}$ inhibited the competition reaction. The gas phase basicities (GB) and proton affinities (PA) were determined by the calculation of the gas phase structures of PAP and protonated PAP. They can be calculated as follows: ${ }^{165]}$

$$
\begin{align*}
& \Delta G=G_{(L H)}-\left[G_{(L)}+G_{\left(H^{+}\right)}\right]  \tag{3.4}\\
& P A=H_{\left(L H^{+}\right)}-\left[H_{(L)}+H_{\left(H^{+}\right)}\right] \tag{3.5}
\end{align*}
$$

The values for the gas phase enthalpy and entropy of protons are:
$H_{\left(H^{+}\right)}=1.48 \mathrm{kcal} / \mathrm{mol}$
$S_{\left(H^{+}\right)}=26.02 \mathrm{kcal} /(\mathrm{mol} * K)$
$G_{\left(H^{+}\right)}=-6.28 \mathrm{kcal} / \mathrm{mol} .{ }^{[166]}$

Figure 3.15: ${ }^{31} \mathrm{P}-\mathrm{NMR}$ ( 121 MHz, THF- $\mathrm{d}_{8}$ ) spectra of the experimental evaluation of 5 a by competition reaction with MTBD and integration of the protonated and free PAP.

To calculate the $\mathrm{p} K_{B H^{+}}$value, the compounds were optimized in the gas phase and their vibrational frequencies were calculated in order to ensure that the optimized structure was a global minimum. Next, the compounds were calculated using a conductor-like polarizable continuum model (CPCM) to simulate solvent interactions. ${ }^{[167]}$ By inserting the GibBS energies of these PAPs into the thermodynamic cycle by Shields et al. (Figure 3.16 and Equation [3.6) the $\mathrm{p} K_{B H^{+}}$value could be calculated. ${ }^{[153]}$

Figure 3.16: Thermodynamic cycle for estimating basicity in solution by ShiELDS and coworkers. ${ }^{153]}$

The basicity can therefore be described by the following equation:

$$
\begin{align*}
\mathrm{p} K_{\left(B H^{+}\right)}= & \mathrm{p} K_{\left(A H^{+}\right)}+\left[G_{g a s}(B)-G_{g a s}(A)-G_{g a s}\left(B H^{+}\right)+G_{g a s}\left(A H^{+}\right)+\right. \\
& \left.\Delta G_{s o l}(B)-\Delta G_{s o l}(A)-\Delta G_{s o l}\left(B H^{+}\right)+\Delta G_{s o l}\left(A H^{+}\right)\right] / 2.303 R T \tag{3.6}
\end{align*}
$$

The results of these experiments and calculations are displayed in Table 3.5.
Table 3.5: Gas phase basicity (GB), proton affinity (PA), measured and calculated $\mathrm{p} K_{B H^{+}}$ values of PAP.

| monoPAP | 5 a | 5b | 5c | 5d | $5 \mathrm{e}^{[138]}$ | $5 \mathbf{f}^{138]}$ | 9 |

| $\mathrm{p} K_{B H^{+}}$(calc.) ${ }^{[\mathrm{c}]}$ | 34.3 | 36.7 | 30.7 | 43.8 | 45.1 | 15.5 |  |
| ${ }^{\text {a Proton affinities and gas }}$ |  |  | phase | basicit | were | calcul | using |
| ${ }^{\mathrm{b}}$ Measured in THF- $\mathrm{d}_{8}$ and correlated to the MeCN scale according to Leito et al. ${ }^{[23]}$ |  |  |  |  |  |  |  |
| ${ }^{c}$ Calculated using $\mathrm{PBE} /$ def2tzvp ${ }^{[153][54]}$ and calculated according to equation 3.6. ${ }^{[153]}$ |  |  |  |  |  |  |  |

From these experiments it can be concluded, that monoPAPs $5 \mathrm{a}-5 \mathrm{~d}$ all exhibit similar $\mathrm{p} K_{B H^{+}}$ ( MeCN ) values of $25 \pm 1$ with $\mathbf{5 b}$ being stronger than $\mathbf{5 a}$ and $\mathbf{5 f}$ being overall the strongest of these as would be expected. Also, as expected, $\mathbf{6 a}$ and $\mathbf{6 b}$ are stronger than their monoPAP analogues 5 a and 5 b and weaker than their trisPAP analogues $\mathbf{7 a}$ and $\mathbf{7 b}$. This is further supported by the calculated $\mathrm{p} K_{B H^{+}}$values, which match the experimental values. This trend can also be seen in the GB and PA of these compounds. monoPAPs 5a-5f have GB of 257$267 \mathrm{kcal} / \mathrm{mol}$ and PA of $265-274 \mathrm{kcal} / \mathrm{mol}$ with $\mathbf{5 f}$ being the strongest of this series. In the row of $5 \mathbf{a}$ to $\mathbf{6 a}$ to $\mathbf{7 a}$ the GB increases by $10-15 \mathrm{kcal} / \mathrm{mol}$ per phosphazene unit corresponding to an increase in basicity of $6-7$ units which matches with SCHWESINGER's battery cell principle. [17]

### 3.1.8 Sterical Parameters

In order to investigate the steric properties of these PAPs, the buried volume as well as the solid and exact cone angles were calculated. The buried volume ( $\% V_{\text {Bur }}$ ) is the amount of space that is occupied by a ligand inside a sphere of a predefined radius ( $3.5 \AA$ ) centered on the metal atom. It was calculated by the use of an online tool SambVca by Cavallo et al. [111] It also allows for the generation of steric maps of the ligands. Other steric parameters that were calculated were the exact cone angle and the solid cone angle developed
by Bilbrey et al. ${ }^{[109[110]}$ The exact cone angle is the apex angle of a cylindrical cone centered on the metal atom of a [PAP-Ni] complex. This angle is different to Tolman's definition of a cone angle, as it allows for flexibility on the bond length of [PAP-Ni]. Closely related is the solid angle $\omega$, which can be described as a measure of the 'shadow' cast by an atom or group of atoms when placed relative to an apex atom, 'a light source'. ${ }^{109[110]}$ They are not bound by a fixed L-M bond length and can be calculated from a crystal or computationally generated structure. The disadvantage of the solid angle approach is, that it treats the ligand as 'frozen' which induces inaccuracies, as ligands are often able to almost freely rotate along low rotational barriers. ${ }^{[108-[110]}$ For the sake of completeness, both cone angles were included. An overview over the cone and solid angles as well as the buried volumes of PAPs can be seen in Table 3.6. The inputs for these calculations were optimized gas phase structures of PAPNi complexes for cone angles and [PAP-AuCl] complexes for buried volumes Notably, the values for $\mathbf{3 2 a}$ and $\mathbf{3 3 a}$ only differ by $0.5 \%$ and $0.1 \%$ from XRD to DFT optimized structures, showing that this method is a reliable measure to compare their buried volumes.

Table 3.6: Calculated cone and solid angles, as well as buried volumes of PAP.

| monoPAP | 5a | 5b | 5c | 5d | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Cone Angle [ $\left.{ }^{\circ}\right]^{[a]}$ | 193.5 | 207.9 | 203.5 | 194.8 | 214.2 |
| Solid Angle [ $\left.{ }^{\circ}\right]^{[a]}$ | 182.2 | 186.7 | 202.9 | 185.6 | 203.8 |
| $\% V_{B u r}{ }^{[b]}$ | 44.1 | 45.6 | 45.9 | 43.1 | 55.1 |
| Bis, trisPAP | 6a | 6b | 13 | 7a | 7b |
| Cone Angle [ $\left.{ }^{\circ}\right]^{[\mathrm{a}]}$ | 194.9 | 216.9 | 237.6 | $203.2{ }^{\text {[85] }}$ | $198.9{ }^{[85]}$ |
| Solid Angle [ $\left.{ }^{\circ}\right]^{[a]}$ | 193.5 | 201.3 | 258.7 | - | - |
| $\% V_{\text {Bur }}{ }^{[\mathrm{b}]}$ | 47.4 | 46.5 | 54.2 | $48.7{ }^{\text {[86] [c] }}$ | $40.9{ }^{\text {86] }}$ |

${ }^{\text {a }}$ Cone angles were calculated according to a method developed by Bilbrey et al. ${ }^{[110]}$ A Mathematica package FindConeAngle or FindSolidAngle developed by the authors was used. ${ }^{[168]}$ The inputs were optimized geometries of $\mathrm{L}-\mathrm{Ni}$ complexes at the PBE/def2tvp level. [153]154]
${ }^{\text {b }}$ Calculated using [L-AuCl] complexes at the $\mathrm{PBE} /$ def2tvp 153 [154] level with SambVca 2.0 ( $\mathrm{r}=3.50 \AA$, Bond radii scaled with 1.17, Hydrogens omitted). [111][12]
${ }^{c}$ Calculated using the crystal structure of $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complex.

PAPs exhibit very high cone angles of around $200^{\circ}$, which surpasses $\mathrm{P} t \mathrm{Bu}_{3}\left(182^{\circ}\right)^{[89]}$ and lies in the same range as Gessner's YPhos (199 $)$. 60 The higher end of cone angles for these compounds can be found on the pyrrolidino and cyclohexyl substituted PAPs 5b, 5c and $\mathbf{6 b}$. Interestingly, the substitution of dimethylamino groups by $t$-butyl groups from 5a to 5 d does not increase the cone angles by a huge amount. $\mathbf{9}$ and $\mathbf{1 3}$ both exhibit extremely high cone angles, as was expected because of their bulky dipp or biaryl substituents. The buried volume follows a similar trend and ranges from $44-55 \% .9$ and 13 are the exceptions again with extremely high buried volumes which are similar to BuchwaLD's biarylphosphines ( $50.9 \%$ for JohnPhos) ${ }^{[169]}$ and Gessner's YPhos (48.5\%). ${ }^{[72]}$ PAPs are also sterically more demanding than Dielmann's IAPs $(35.3 \% ; 36.2 \%)^{[8][169]}, \mathrm{P}(\mathrm{Ad})_{3}(40.5 \%)^{[170]}$ and $\mathrm{P} t \mathrm{Bu}_{3}$

[^7](38.1\%). ${ }^{[169]}$ As already mentioned, steric maps of these PAPs were obtained by the use of SambVca which allows some insight into the catalytic pockets that may be formed with these compounds. Figure 3.17 shows the sterical maps of $\mathbf{5 a}$ to $\mathbf{5 d}$ which represent the filled space of a sphere with a radius of $3.5 \AA$. The $\mathrm{P}-\mathrm{Au}$ axis is oriented into the plane and defined as the $\mathbf{z}$-axis. From this, the difference between monoPAPs can be seen clearly as both $\mathbf{5 c}$ and $\mathbf{5 b}$ have more bulky substituents on the phosphazene core, resulting in a higher hindrance in the western sectors of these sterical maps.

Figure 3.17: Sterical maps of $\mathbf{5 a}$ (top left), $\mathbf{5 b}$ (top right), $\mathbf{5 c}$ (bottom left) and 5d (bottom right). The trivalent phosphorus atom is centered in the middle of the sterical map and the molecule is viewed along the $\mathrm{P}-\mathrm{Au}(\mathrm{z})$ axis.

Figure 3.18 shows the sterical maps of bisPAPs $\mathbf{6 a}$ and $\mathbf{6 b}$. The increase in steric demand from mono- to bisPAP is clearly visible. Again, the pyrrolidino substituents of $\mathbf{6 b}$ are more sterically demanding than the dimethylamino substituents of $\mathbf{6 a}$.

Figure 3.18: Sterical maps of $\mathbf{6 a}$ (left), $\mathbf{6 b}$ (right). The trivalent phosphorus atom is centered in the middle of the sterical map and the molecule is viewed along the $\mathrm{P}-\mathrm{Au}(\mathrm{z})$ axis.

Figure 3.19 shows the sterical maps of $\mathbf{9}$ and $\mathbf{1 3}$. These two PAPs show very blatantly their difference in sterics in comparison to other PAPs. Phosphoramidite 9 features very high
sterical demand, stemming from its dipp groups in the eastern sector of the map. Bisaryl 13 is even more extreme, both the northern as well as the southern sector are sterically shielded by the phosphazenyl and biaryl substituents. However, good accessibility from the eastern and western side of the ligand can be seen. This is the catalytic pocket stabilized by $\pi$ arene interactions. The same can be said for 9 to a lesser extent.

Figure 3.19: Sterical maps of $\mathbf{9}$ (left) and $\mathbf{1 3}$ (right). The trivalent phosphorus atom is centered in the middle of the sterical map and the molecule is viewed along the P-Au ( z ) axis.

Synthetically, [AuClPxP] $(\mathrm{x}=1,2)$ compounds were obtained by addition of $\left[\mathrm{PPh}_{3} \mathrm{AuCl}\right]$ or $\left[\mathrm{SMe}_{2} \mathrm{AuCl}\right]$ under the exclusion of light after stirring for one hour or overnight (Scheme (3.10). Through removal of the solvent in vacuo and subsequent redissolving in hot pentane, the compounds were isolated. It is noteworthy to add, that slow cooling to $-30^{\circ} \mathrm{C}$ is required in order to ensure the product is free of $\mathrm{PPh}_{3}$.

Scheme 3.10: Synthesis of 32a and 33a.

Single crystals suitable for XRD of 32a and 33a (Figure 3.20) were obtained by slowly cooling a saturated pentane solution to $-30^{\circ} \mathrm{C} . \mathbf{3 2 a}$ features a P1-Au1 bond length of $2.253 \AA$ and $\mathbf{3 3}$ a of $2.256 \AA$. This is shorter than $\mathrm{PPh}_{3}-\mathrm{AuCl}$ with $2.231 \AA \AA^{[171]}$ and comparable to GESSNER's $o \mathrm{TolYPCy}_{2}$ with $2.254 \AA$. ${ }^{[72]}$ The Cl1-Au1-P1 bond angles are all close to the expected $180^{\circ}$. The P1-N1 bonds are shortened relative to their free base forms.

Figure 3.20: Molecular structures of 32a (left) and 33a (right). Ellipsoids are set at 50\% probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles [ ${ }^{\circ}$ ]: 32a: N1-P1 1.62(3), N1-P2 1.57(3), P1-Au1 2.25(9), Cl1-Au1 2.31(1), P1-Au1-Cl1 179.2(4), 33a: N1-P2 1.57(7), Cl1-Au1 2.34(2), N1-P1 1.61(7), P1-Au1 2.26(2), P1-Au1-Cl1 175.6(9).

### 3.1.9 Mulliken Orbital Charge Population Analysis

For a closer investigation into the nature of the donor capabilities, a series of calculations was performed to determine the strength of $\sigma$-donation and $\pi$-acceptance for these ligands. This was previously done for the heavier analogues of NHCs: heterocyclic tetrylenes $\left(\mathrm{Ar}_{2} \mathrm{NENAr}_{2}\right.$ with $\mathrm{E}=\mathrm{Ge}, \mathrm{Sn}, \mathrm{Pb})$. ${ }^{[172]}\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes were calculated using $\mathrm{PBE} /$ def2tvp and the $\mathrm{P}(\mathrm{III})-\mathrm{Ni}$ axis was oriented along the z -axis. ${ }^{[153 \mid 154]}$ The $\sigma$-donation may be measured as the change of the Mulliken charges in $s(P)$ and $p_{z}(P)$ orbitals from free ligand to nickel complex. The $\pi$-acceptance can likewise be calculated by the differences in $p_{x}(P)$ and $p_{y}(P)$ orbitals. The fragmentation as well as the bond energy were calculated as the breakage of the P-Ni bond along the z-axis with unrelaxed (non-optimized) and relaxed (optimized) fragments, respectively. An overview of these results is given in Table 3.7.

Table 3.7: Overview over the changes in the Mulliken orbital charge population in $\pi$ and $\sigma$ orbitals of PAPs as well as the fragmentation and bond energy of $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ fragments.

| Ligand $^{[\mathrm{a}]}$ | $\Delta S^{[\mathrm{b}]}$ | $\Delta P \sigma^{[\mathrm{b}]} \Delta P \pi^{[\mathrm{b}]}$ | $\sum\|\Delta\|^{[\mathrm{c}]} \pi / \sigma^{[\mathrm{d}]}$ | $\mathrm{E}_{\mathrm{frag}}[\mathrm{kcal} / \mathrm{mol}]^{[\mathrm{e}]} \mathrm{E}_{\mathrm{bond}}[\mathrm{kcal} / \mathrm{mol}]^{[\mathrm{e}]}$ |  |  |
| :--- | :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathbf{5 a}$ | 0.06 | 0.47 | -0.08 | 0.44 | 0.16 | 54.1 |
| $\mathbf{5 b}$ | 0.08 | 0.47 | -0.11 | 0.45 | 0.19 | 54.3 |
| $\mathbf{5 c}$ | 0.09 | 0.49 | -0.06 | 0.52 | 0.10 | 54.9 |
| 5d | 0.06 | 0.48 | -0.07 | 0.48 | 0.13 | 52.7 |
| $\mathbf{9}$ | 0.15 | 0.11 | 0.03 | 0.23 | -0.11 | 52.3 |
| $\mathbf{6 a}$ | 0.10 | 0.49 | -0.09 | 0.49 | 0.16 | 59.4 |
| $\mathbf{6 b}$ | 0.16 | 0.42 | -0.09 | 0.49 | 0.15 | 61.5 |
| $\mathbf{1 3}$ | 0.19 | 0.39 | -0.07 | 0.52 | 0.11 | 56.4 |
| $\mathbf{7 a}$ | 0.17 | 0.37 | 0.01 | 0.54 | 0.02 | 68.4 |
| 7b | 0.24 | 0.33 | 0.00 | 0.56 | 0.00 | 66.4 |
| $\mathbf{P t B u}_{\mathbf{3}}$ | 0.06 | 0.50 | -0.04 | 0.52 | 0.07 | 46.7 |

${ }^{\mathrm{a}}$ The inputs were optimized geometries of $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes at the $\mathrm{PBE} /$ def2tvp level. ${ }^{153 \mid 154]}$
${ }^{\mathrm{b}} \Delta S, \Delta P \sigma$ and $\Delta P \pi$ values are the differences in Mulliken charge populations of the orbitals between PAP and $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ at the central phosphorus atom. $\Delta P \sigma$ orbitals are defined as $\mathrm{p}_{\mathrm{z}}$ orbitals along the axis of $\mathrm{P}-\mathrm{Ni} ; \Delta P \pi$ orbitals are defined as the sum of $\mathrm{p}_{\mathrm{x}}$ and $\mathrm{p}_{\mathrm{y}}$ orbitals perpendicular to said axis.
${ }^{c} \sum|\Delta|$ is the sum of $\Delta S+\Delta P \sigma$ and $\Delta P \pi$ values.
${ }^{\mathrm{d}} \pi / \sigma$ is the ratio of $\Delta P \pi /(\Delta S+\Delta P \sigma)$.
${ }^{e} \mathrm{E}_{\text {frag }}$ is the difference in energy of the unrelaxed fragments of PAP and $\mathrm{Ni}(\mathrm{CO})_{3} ; \mathrm{E}_{\text {bond }}$ is the energy of the relaxed fragments.

It can be deduced, that the introduction of alkyl groups into PAPs (5a-5d) increases their $\pi$ acceptance character, however it is still very low, about double that of $\mathrm{P} t \mathrm{Bu}_{3}$, a ligand known as an almost pure $\sigma$-donor. TrisPAPs ( $\mathbf{7 a}$ and $\mathbf{7 b}$ ) are pure $\sigma$-donors and display virtually no $\pi$-acceptance. The sum of donation increases for each added phosphazenyl group, as does the bond and fragmentation energy. Donation abilities of 5a-5d are comparable, but a substitution of amines to alkyl groups on the phosphazene core seems to increase $\sigma$-donation by a small amount. $\sigma$-Donor and $\pi$-acceptor characteristics are consistent across monoPAPs. $\mathbf{9}$ is a much weaker $\sigma$-donor, but is a better $\pi$-acceptor than $\mathbf{5 a - 5 d}$. This is also reflected in its very high TEP as discussed earlier. Fragmentation as well as bond energy lie in the range of its mono substituted analogues $\mathbf{5 a - 5 d}$. BisPAPs ( $\mathbf{6 a}$ and $\mathbf{6 b}$ ) lie between its mono- and trisPAP analogues, as expected. Biaryl PAP 13 behaves similarly to its bisPAP analogues despite its obvious sterical differences, suggesting that the electronic properties are mostly set by the phosphazenyl core.

### 3.2 Summary

The class of phosphazenyl phosphines (PAP) was extended to readily available monoPAPs $\mathrm{R}_{3} \mathrm{P}=\mathrm{N}-\mathrm{P} t \mathrm{Bu}_{2}(5 \mathrm{a}-5 \mathrm{~d})$ which exhibit similar cone angles and buried volumes as $\mathrm{P} t \mathrm{Bu}_{3}$ while simultaneously exceeding it in terms of donor ability. A mono phosphazenyl phosphoramidite ligand 9 was introduced in order to provide a PAP with higher $\pi$-acceptor character compared to $\mathbf{5 a} \mathbf{- 5 d}$. With bisPAP representatives $\left(\mathrm{R}_{3} \mathrm{P}=\mathrm{N}\right)_{2} \mathrm{P} t \mathrm{Bu}(\mathbf{6 a - 6 b})$, the missing gap to trisPAPs was established. An analogue to BUCHWALD's biarylphosphines 13 could be synthesized and characterized (Figure 3.21). The synthetic strategies allow the extension of the PAP construction kit via readily available, easily modifiable building blocks. Electronic properties of all new PAP ligands were investigated and correlated according to their experimental and calculated TEPs of $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes and ${ }^{1} J_{(P, S e)}$ coupling constants of corresponding P-selenides. Their P-basicity was calculated and experimentally measured with the help of a reference bases. Basicity and donor characteristics of monoPAPs are in the same range as prominent ligands from the substance classes of NHCs and YPhos. P-basicity of monoPAPs is comparable to N -basicity of classical Schwesinger- $\mathrm{P}_{2}$ bases. BisPAPs are superior with respect to their basicity and donor character and are comparable to IAP ligands. A computational Mulliken population study analyzing the $\sigma$-donor and $\pi$-acceptor metal ligand bond interactions added additional insight for all these findings. Stability of PAPs towards acidic and basic aqueous conditions was evaluated and a study revealing their potential to act as C-nucleophiles versus as a base was performed.

## 4 Transition Metal Catalysis with PAP Superbases

### 4.1 Results and Discussion

Transition metal catalyzed cross coupling reactions have been in the focus of the scientific community for many years. Since their first iteration, there have been huge advancements both in ligand design and understanding of the underlying mechanisms. ${ }^{[173]}$ The SuzukiMiyaura reaction has been widely used for the synthesis of natural products, liquid crystals and pharmaceuticals. ${ }^{[174-177]}$ Similarly, the palladium catalyzed Buchwald-Hartwig amination reaction can be used for a wide variety of substrates and can be performed on an industrial scale. $\frac{[178-180]}{[180}$ Another reason for the continued popularity of these reactions is the comparably low toxicity of its products and byproducts by avoiding for example tin organyls. ${ }^{[181] \mid 182]}$ Mechanistically, these cross coupling reactions function quite similarly. The first step generally involves the generation of the active metal species by reduction of a precatalyst (Figure 4.1). This [ $\left.\mathrm{L}_{\mathrm{n}} \mathrm{Pd}\right](\mathrm{n}=1$ or 2 ) complex undergoes oxidative addition with ArX ( $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}$, I, OTf) leading to $\mathrm{L}_{\mathrm{n}} \mathrm{Pd}(\mathrm{Ar}) \mathrm{X}$. Through transmetallation with RM (M $\left.=\mathrm{B}(\mathrm{OH})_{2}, \mathrm{Mg}, \mathrm{Sn}, \mathrm{Zn}\right) \mathrm{L}_{\mathrm{n}} \mathrm{Pd}(\mathrm{Ar}) \mathrm{R}$ is generated. Reductive elimination liberates ArR and regenerates [ $\mathrm{L}_{\mathrm{n}} \mathrm{Pd}$ ]. [183]

Figure 4.1: General mechanism for a palladium catalyzed cross coupling reaction. [183]

One of the most dominant ligand classes for these transformations are bulky electron rich phosphines. Buchwald et al. showed that the introduction of a biaryl moiety offers the
needed sterical hindrance to promote ligand dissociation into $14 \mathrm{VE}\left[\mathrm{L}_{2} \mathrm{Pd}\right]$ and $12 \mathrm{VE}[\mathrm{L}-\mathrm{Pd}]$ complexes, while the electron rich phosphine promotes the oxidative addition step. ${ }^{184}$-187] Furthermore, the use of precatalysts with a ligand to palladium ratio of 1:1 promotes the formation of a highly active monoligated [L-Pd] species. ${ }^{[188]}$ BUCHWALD's fourth generation (G4) of precatalysts demonstrate this concept very well (Scheme 4.1). These metallacycles release [L-Pd] and a carbazole derivative under basic conditions with a weak base at low temperatures. [189]190] Several groups make use of these monoligated species like NoLAN with NHC complexes of the type $\left[\mathrm{Pd}(\mathrm{NHC})\left(\eta^{3}-\mathrm{allyl}\right) \mathrm{Cl}\right]^{[191-193]}$, Fu with $\left[\mathrm{Pd}\left(\mathrm{P} t \mathrm{Bu}_{3}\right)_{2}\right]^{[130]}$ as well as GeSSNER with YPhos $\left[\mathrm{Pd}(\mathrm{YPhos})\left(\eta^{3}-t \mathrm{Bu}-\mathrm{ind}\right) \mathrm{Cl}\right](t \mathrm{Bu}-\mathrm{ind}=1$-tert-butylindenyl). 71]194-196] DiElmann and Verkade show that IAPs and phosphazenes can be utilized as ligands for these transformations as well. $79[80[129]$ With the intention to expand the scope of available ligands to include phosphazenyl phosphines as an example of highly electron rich and bulky ligands, screening reactions were performed.

### 4.1.1 Palladium Complexes of PAP

To understand the behavior of these ligands towards different palladium sources, a range of palladium (0) and (II) sources were reacted with various mono-, bis- and trisPAPs in toluene at room temperature. As evident from Scheme 4.2, reactions with $\mathrm{PdCl}_{2}$ and $\left[(\mathrm{MeCN})_{2} \mathrm{PdCl}_{2}\right]$ yielded the chlorophosphonium PAP chlorides ([Cl-PAP]Cl) as well as palladium black and a variety of side products (Reactions 1,2 and 8 ). MonoPAP 5a yielded, when $\mathrm{Na}_{2} \mathrm{PdCl}_{4}$ is employed, the palladium complex $\left[(\mathrm{PAP})_{2} \mathrm{PdCl}_{2}\right](\mathbf{3 6})$ as well as a variety of side products. These include the chlorophosphonium PAP as well as palladium black (Reaction 9). If $\mathrm{PdCl}_{2}$ was used, only chlorophosphonium PAP and palladium black were isolated (Reaction 8). The reaction between trisPAP 7a and $\left[\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ yielded a mixture of $\left[\mathrm{PAP}-\mathrm{Pd}-\mathrm{PPh}_{3}\right]$, chlorophosphonium PAP and $\mathrm{PPh}_{3}$ (Reaction 3). The reaction between trisPAP 7a and $\left[\mathrm{Pd}\left(\mathrm{P} t \mathrm{Bu}_{3}\right)_{2}\right]$ yielded a mixture of $\left[\mathrm{PAP}-\mathrm{Pd}-\mathrm{P} t \mathrm{Bu}_{3}\right]$ and $\mathrm{P} t \mathrm{Bu}_{3}$ (Reactions 4 and 5). ${ }^{[86]}$

TrisPAP 7a reacted with $\left[\mathrm{Pd}\left(\eta^{3}-\right.\right.$ allyl $) \mathrm{Cl}_{2}$ to form the corresponding allyl complex (Reaction 6) and a variety of side products. $\left[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}_{2}\right.$ reacted, in the case of bisPAP 6a to palladium black and chlorophosphonium PAP (Reaction 7). If monoPAP 5a was employed, a quantitative conversion to the corresponding $\left[\mathrm{PAP}-\mathrm{Pd}\left(\eta^{3}-\operatorname{cinn}\right) \mathrm{Cl}\right]$ complex could be observed (Reaction 10). It is reasonable to assume, that the reason no $(\operatorname{PxP})_{2}-\mathrm{Pd}(\mathrm{X}=2$ or 3$)$ complexes could be isolated, is that the complexes do not possess a sufficient amount of $\pi$-backbonding capabilities to stabilize $\operatorname{Pd}(0)$ and therefore hinder the generation of palladium black. The fact that $\left[\mathrm{P}_{3} \mathrm{P}-\mathrm{Pd}-\mathrm{L}\right]\left(\mathrm{L}=\mathrm{PPh}_{3}, \mathrm{P} t \mathrm{Bu}_{3}\right)$ complexes exist, supports this hypothesis, as the $\pi$-acidity of $\mathrm{PPh}_{3}$ or $\mathrm{P} t \mathrm{Bu}_{3}$ may compensate the extreme $\sigma$-donor character of the PAP ligand. This is also the reason, why monoPAP reacts much more selectively with palladium precursors, especially $\left[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}_{2}\right.$ as it possesses better $\pi$-backbonding capabilities, as was shown in a previous section.

Scheme 4.2: Reaction of various palladium sources with various PAPs. 7a is referred to as $\mathrm{dmaP}{ }_{3} \mathrm{P}, \mathbf{6 a}$ as $\mathrm{dmaP}_{2} \mathrm{P}$ and $\mathbf{5 a}$ as $\mathrm{dmaP}_{1} \mathrm{P}$ as a shortened notation.

The reaction progress of monoPAP 5a with $[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}$ to $\mathbf{3 5 a}$ can be observed by ${ }^{31} \mathrm{P}$ NMR spectroscopy as the signals for $\mathbf{5 a}$ shift from $85.4\left(\mathrm{P}^{\mathrm{II}}\right)$ and $31.4 \mathrm{ppm}\left(\mathrm{P}^{\mathrm{V}}\right)$ to $96.6\left(\mathrm{P}^{\mathrm{III}}\right)$ and $13.4 \mathrm{ppm}\left(\mathrm{P}^{\mathrm{V}}\right)$ in $\mathbf{3 5 a}$. This is accompanied by a reduction in the ${ }^{2} J_{(P, P)}$ coupling constant from 100.5 Hz to 6.5 Hz (Scheme 4.3). In order to investigate the activation of this palladium (II) precatalyst an NMR experiment was designed to simulate cross coupling conditions. The complex was reacted with an excess of $\mathrm{KO} t \mathrm{Bu}$ and ${ }^{31} \mathrm{P}$-NMR spectra were taken. No changes could be detected at room temperature after 1 h indicating an activation barrier in order to generate the active $\mathrm{Pd}(0)$ species. Heating of this mixture to $80^{\circ} \mathrm{C}$ for 30 min generated a new set of signals in the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum. A set of virtual triplets at 95.3 and 20.7 ppm with a coupling constant of 16.5 Hz appeared, which correspond to a homoleptic [ $\mathrm{L}_{2} \mathrm{Pd}$ ] complex analogous to the Fu catalyst $\left[\operatorname{Pd}\left(\mathrm{P} t \mathrm{Bu}_{3}\right)_{2}\right]$ (Figure 4.2). Virtual coupling may appear between two nuclei, in this case phosphorus, when the difference in the chemical shift is comparable to their coupling constants. It appears as if in this AA' XX ' spin system, X or X ' (the trivalent phosphorus atoms) couple to both A and A' (the pentavalent phosphorus atoms), while in
fact, they only couple to A or A' respectively. These two doublets overlap to form this virtual triplet. The $\operatorname{Pd}(0)$ species was quenched by addition of phenyl iodide to induce the oxidative addition, resulting in a new set of doublets at 98.0 and 14.0 ppm .

Scheme 4.3: Synthesis of 35a, $\mathbf{3 6}$ and $\mathbf{3 7}$.

Figure 4.2: ${ }^{31} \mathrm{P}-\mathrm{NMR}(121 \mathrm{MHz}$, toluene) spectrum of the reaction of $\mathbf{3 5 a}$ (bottom) with $\mathrm{KO} t \mathrm{Bu}$ (middle, excess) and phenyl iodide (top, excess).

35a is stable as a solid under air for several months. 38 was obtained as a decomposition product of $\mathbf{3 5 a}$ with bridging chloride ligands under elimination of the cinnamyl moiety (Scheme 4.4). It was reported by Sigman et al. that a solution of $\left[(\mathrm{IMes})-\mathrm{Pd}\left(\eta^{3}-\right.\right.$ allyl $\left.) \mathrm{Cl}\right]$ reacted to form $\left[(\mathrm{IMes}) \mathrm{PdCl}(\mu-\mathrm{Cl}]_{2}\right.$ upon addition of an ethereal HCl solution. ${ }^{[197]}$ This explains the formation of $\mathbf{3 8}$ as a solution of 35a was most likely hydrolyzed by traces of HCl or onium chlorides.

Scheme 4.4: Synthesis of $\mathbf{3 7}$ and possible decomposition pathway of $\mathbf{3 5 a}$ to $\mathbf{3 8}$.

Depending on the ligand, two possible active catalytic species can be generated, either a 14 electron $\left[\mathrm{L}_{2} \mathrm{Pd}\right]$ or a 12 electron [L-Pd] complex ${ }^{\text {a }}$ The 12 electron complex has been proven to be kinetically more active than the thermodynamically more stable 14 electron complex. ${ }^{[199]}$ These 12 electron complexes are generated by sterically demanding ligands. ${ }^{[200[201]}$ Due to their electronically unsaturated nature, they cannot be generated in situ in the reaction mixture, but must be generated from precatalysts with a $1: 1$ ratio of ligand to palladium by reductive elimination. ${ }^{[202]}$ Various groups have exploited these 12 electron complexes by the

[^8]utilization of a variety of precatalysts. Nolan and Gessner have been employing complexes of $\left[\mathrm{L}-\mathrm{Pd}\left(\eta^{3}-\right.\right.$ allyl $\left.) \mathrm{Cl}\right]$ for $\mathrm{NHCs}{ }^{[203]}$ and YPhos respectively. ${ }^{[71]}$ The introduction of bulkier groups on the allyl core such as phenyl and $t$-butylindenyl by HAZARI has proven to facilitate the reductive elimination towards the $[\mathrm{L}-\mathrm{Pd}]$ species by hindering the generation of unwanted $\operatorname{Pd}(\mathrm{I})$ dimers. ${ }^{[183[204-206]}$ Buchwald phosphines follow a different route towards the generation of these 12 electron complexes via the reduction of palladacycles. ${ }^{[207]}$ Organ introduced PEPPSI (pyridine-enhanced precatalyst preparation stabilization and initiation) precatalysts featuring a [ $\mathrm{NHC}-\mathrm{PdCl}_{2}$-pyridine] unit. 202[208] While each of these precatalysts undergoes a different mechanism for the generation of the active species, a similar mechanism to the ones suggested by Nolan or Poater who investigated $\left[\mathrm{Pd}(\mathrm{NHC})\left(\eta^{3}-\mathrm{R}\right.\right.$-allyl $\left.) \mathrm{Cl}\right]$ complexes is plausible for monoPAPs (Scheme 4.5, path b). [209]

Scheme 4.5: Plausible mechanistic pathways for the generation of [monoPAP-Pd] via reductive elimination at precatalyst 35a. ${ }^{209]}$

Four mechanistic pathways a), b), c) and d) towards activation of the precatalyst are suggested. Path a) describes first, a ligand exchange between $\mathrm{Cl}^{-}$and an alkoxide capable of $\beta$-H elimination, in this case $\mathrm{OCH}_{3}^{-}$. According to HAZARI et al. this may occur in an associative or dissociative pathway, depending on the substitutents on the allyl moiety. [206] A H -atom migration, followed by a $\beta$ - H elimination generates the desired [ $\mathrm{L}-\mathrm{Pd}$ ], an alkene and formaldehyde. This was described in alcoholic solvents, but may be applicable if primary or secondary alkoxides are employed as the base. Nolan reports a mechanism where the base, in this case $\mathrm{KO} t \mathrm{Bu}$, attacks at the coordinated allyl moiety as a nucleophile. Subsequent reductive elimination generates [L-Pd] and allyl-OtBu (Path b). 210] MELVIN et al. suggests a different route, where a direct attack of an alkoxide nucleophile ( $\mathrm{RO}^{-}, \mathrm{R}=$ allyl, $\mathrm{H})$ at the Pd-activated allyl moiety followed by reductive elimination generates the free [L$\mathrm{Pd}]$ (Path c). 211] PoAtER et al. calculated the mechanism for this activation with a series of $\left[\mathrm{Pd}(\mathrm{NHC})\left(\eta^{3}\right.\right.$-R-allyl $\left.) \mathrm{Cl}\right]\left(\mathrm{R}=\mathrm{H}, \mathrm{Me}, \mathrm{Me}_{2}, \mathrm{Ph}\right)$ precatalysts with a variety of substituents on the allyl moiety. ${ }^{[209]}$ They concluded, that the concerted pathway c) is unlikely as they were unable to find a transition state. This does not mean that this pathway is not possible, it only means that in their specific case it was unlikely. Pathway b) is initiated by the substitution of the chloride substituent by $-\mathrm{O} t \mathrm{Bu}$, but they note, that this step is not rate determining, as the energy barrier is minimal. Much more impact towards the thermodynamic stability
of the intermediates is determined by the allyl backbone, with cinnamyl being the most stable intermediate of the set. The rate determining step was determined to be the reductive elimination, which means, that the stabilization of the transition state has the highest effect on the overall generation of [L-Pd]. Path d) describes the transmetallation of the precatalyst with an arylboronic acid under Suzuki-MiYaura reaction conditions. The subsequent reductive elimination yields the desired [L-Pd] complex and the olefin $\mathrm{ArCH}=\mathrm{CHCH}_{2} \mathrm{R}$ ( R $=\mathrm{Ph}) .{ }^{[212[213]}$ This pathway does require the usage of a base, but does allow the option to employ mild bases such as $\mathrm{K}_{2} \mathrm{CO}_{3}$ which are compatible with most organic substrates, unlike paths a) to c) which need stronger bases. All four mechanistic pathways are possible, depending on the ligand and the substituents on the allyl moiety, as well as the solvent. However, the reductive elimination is the rate determining step in all four cases and the stabilization of the corresponding transition states should be imperative in the design of new systems. It should be noted, that the generated [L-Pd] complexes may coordinate to the eliminated olefins to $[\operatorname{LPd}($ olefin $)]$ type complexes but, upon entry into the catalytic cycle, these olefins are easily released.

### 4.1.2 Crystal Structures of Palladium Complexes

Single crystals of four different palladium complexes of monoPAP 5a could be obtained. Firstly, $\mathbf{3 5 a}$ was obtained by reaction of $\mathbf{5 a}$ with $\left[\mathrm{Pd}\left(\eta^{3}-\operatorname{cinn}\right) \mathrm{Cl}_{2}\right.$ in $\mathrm{Et}_{2} \mathrm{O}$ and slow cooling of the ethereal solution to $-30{ }^{\circ} \mathrm{C}$ (Figure 4.3). The second structure, 36, was obtained by reaction of $\mathbf{5 a}$ with $\mathrm{Na}_{2} \mathrm{PdCl}_{4}$ in toluene and subsequent slow evaporation of the solvent (Figure4.4). Thirdly, the FU analogue 37 was obtained by slow cooling of an ethereal solution of $\mathbf{3 5 a}$ after reaction with $\mathrm{KO} t \mathrm{Bu}$ at $60^{\circ} \mathrm{C}$ for 1 h (Figure 4.5). Lastly, $\mathbf{3 8}$, a compound with bridging chlorides was obtained as a decomposition product of an ethereal solution of $\mathbf{3 5 a}$ after several months (Figure 4.6).

Figure 4.3: Molecular structure of 35a. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles $\left[{ }^{\circ}\right]$ : P1-Pd1 2.314(5), P1-N1 1.635(16), N1-P2 1.562(17), Pd1-Cl1 2.370(5), Pd1-C11 2.312(18), Pd1-C10 2.174(19), Pd1-C9 2-11(2); P1-N1-P2 145.5(12).

Figure 4.4: Molecular structure of 36. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles $\left[{ }^{\circ}\right]$ : Pd1-P1 2.4168(5), Pd1-Cl1 2.3008(5), P1-N1 1.6224(16), P2-N2 1.6559(19); P1-Pd1-P1 180.0, Cl1-Pd1-P1 87.066(18).

35a features a P-Pd bond length of $2.314 \AA$ and a $\mathrm{Pd}-\mathrm{Cl}$ bond length of $2.370 \AA$ which is comparable to similar $\left[\mathrm{Pd}(\mathrm{L})\left(\eta^{3}\right.\right.$-cinn $\left.) \mathrm{Cl}\right]$ complexes $\left(\mathrm{L}=\mathrm{PCy}_{3} \mathrm{P}-\mathrm{Pd}: 2.299 \AA, \mathrm{Pd}-\mathrm{Cl}\right.$ $2.373 \AA ;{ }^{[214]} \mathrm{L}=\mathrm{PCy}_{3} \mathrm{C}(\mathrm{Me}) \mathrm{PCy}_{2}=$ keYPhos, $\left.\mathrm{P}-\mathrm{Pd}: 2.317 \AA, \mathrm{Pd}-\mathrm{Cl}: 2.386 \AA\right)$. ${ }^{[71]} \mathbf{3 6}$ crystallizes in the orthorhombic space group $\mathrm{P}_{\text {bca }}$. It features a Pd1-P1 bond length of $2.417 \AA$ while in $\left[\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{PdCl}_{2}\right]$ it is $2.337 \AA$ and $\mathrm{Pd} 1-\mathrm{Cl1}$ distances of $2.301 \AA$ compared to $2.291 \AA$ in $\left[\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{PdCl}_{2}\right]$. ${ }^{[215]}$ The central palladium atom is, as expected, in a square planar arrangement with bond angles of $180^{\circ}$ for P1-Pd1-P1 and Cl1-Pd1-Cl1. The phosphazenyl substituents exhibit a torsion angle N1-P1-P1-N1 of $180^{\circ}$.

Figure 4.5: Molecular structure of $\mathbf{3 7}$. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles [ $\left.{ }^{\circ}\right]$ : P1-N1 1.652(5), P2-N1 1.544(5), P1-Pd1 2.2910(17), Pd1-P3 2.3031(18), P3-N5 1.666(6), N5-P4 1.549(5); P3-Pd1-P1 171.49(6), N5-P3-P1-N1 -152.53(4).

The P1-Pd bond length of $\mathbf{3 7}$ of $2.291 \AA$ and the P2-Pd bond length of $2.303 \AA$ is slightly longer than the P-Pd bond in $\left[\mathrm{Pd}\left(\mathrm{P} t \mathrm{Bu}_{3}\right)_{2}\right](2.280 \AA)$ and shorter than in the heteroleptic complex $\left[\mathrm{dmaP}_{3} \mathrm{P}-\mathrm{Pd}-\mathrm{PPh}_{3}\right](2.357 \AA)$. ${ }^{86[216]}$ The $\mathrm{P} 1-\mathrm{Pd}-\mathrm{P} 2$ bond angle of $171.5^{\circ}$ is distorted compared to the $180^{\circ}$ of the aforementioned structures. The P1-C1 bond length of $1.893 \AA$ is lower than the FU analogue ( $1.915 \AA$ ). The two phosphazenyl substituents exhibit a torsion angle N1-P1-P3-N5 of $152^{\circ}$ in comparison to the torsion angle of the $t$-butyl groups of $\left[\operatorname{Pd}\left(P t B u_{3}\right)_{2}\right]$ with $60^{\circ}$. These differences may be attributed firstly, because 5 a is a better $\sigma$-donor than $\mathrm{P} t \mathrm{Bu}_{3}$ (see Section Donor Properties) and secondly because of the increased sterical strain that is introduced into the structure by the two phosphazenyl substituents.

Figure 4.6: Molecular structure of 38. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles [ $\left.{ }^{\circ}\right]$ : Pd1P1 2.2596(3), P1-N1 1.5964(1), N1-P2 1.5522(1), Pd1-Cl2 2.2976(3), Pd1-Cl1 2.4798(3); P1-Pd1-Cl1 176.590(1).

38 crystallizes in the monoclinic space group $P_{1} 2_{1 / c}$. It possesses a P1-Pd1 bond length of $2.260 \AA$ and a Pd1-Cl2 bond length of $2.298 \AA$. The bond length of the bridging chlorides $\mathrm{Pd} 1-\mathrm{Cl} 1$ is $2.313 \AA$. In comparison, an IMes analogue of this crystal $\left(\left[(\mathrm{IMes}) \mathrm{PdCl}(\mu-\mathrm{Cl}]_{2}\right)\right.$ possesses a C1-Pd1 bond length of $1.955 \AA$ and Pd1-Cl1 bond length of $2.276 \AA$ while the bond length of the bridging chlorides to Pd 1 is $2.332 \AA .{ }^{[197]} 38$ is completely planar along the P-Pd-Cl-Pd-P axis and exhibits $\mathrm{C}_{2 h}$ symmetry. In contrast to this, its IMes analogue is twisted along this axis by $27^{\circ}$ and is asymmetric. The palladium atoms are distanced $3.6258 \AA$ apart from each other, while in IMes they are only $3.298 \AA$ apart. An overview over some bond lengths of various palladium (0) and palladium (II) complexes is given in Table 4.1.

### 4.1.3 Suzuki-Miyaura reactions

In order to test these ligands about their applicability in cross coupling reactions, they were employed in a palladium catalyzed Suzuki-Miyaura coupling of phenylboronic acid with $p$-toluyl chloride. The halide was chosen consciously as chloride in order to provide a bet-
ter comparison to its parent ligand $\mathrm{P} t \mathrm{Bu}_{3}$, which is able to catalyze this transformation. ${ }^{130}$ Phenylboronic acid was chosen for its simplicity, atom efficiency and high reactivity in the transmetalation. They are more prone to protodeboronation or oxidation compared to other commonly used boron reagents like boronic esters, $N$-coordinated boronates or trifluoroborates, but these require prior hydrolysis to the boronic acid (Figure 4.7). ${ }^{[213]}$ Most often this is achieved by addition of water to the reaction mixture, which was to be avoided with PAPs. ${ }^{[218]}$

Figure 4.7: Overview over different boron reagents for the Suzuki-Miyaura coupling.

Every ligand was screened under the same conditions with palladium cinnamyl chloride as the palladium source, which was premixed with the ligand before addition (Scheme 4.6). It can be concluded, that monoPAPs 5a-5d perform reasonably well under these conditions, with $\mathbf{5 a}$ providing an almost quantitative yield. Interestingly, $\mathbf{9}$ also performed well with a yield of $73 \%$, suggesting that not only the donor ability of these ligands is important. A certain degree of $\pi$-backbonding has to be present to stabilize $\operatorname{Pd}(0)$ intermediates to avoid decomposition to palladium black. With higher substituted PAPs 6a and $\mathbf{6 b}$ this phenomenon can be observed, as no conversion to the desired product could be detected, only the generation of palladium black. The same can be said for trisPAPs $\mathbf{7 a}$ and $\mathbf{7 b}$. In direct comparison, $\mathrm{P} t \mathrm{Bu}_{3}$ did not yield any biaryl product, however, if $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ was used as the base and dioxane as the solvent, a yield of $85 \%$ could be achieved, which is in line with the reported literature. 130 Based upon these promising results, further investigations into these reactions were made. Screening reactions to determine the best base, solvent, palladium source and ligand were performed to optimize this reaction.

Scheme 4.6: Screening of different PAP ligands in a Suzuki-Miyaura cross coupling reaction with $p$-toluyl chloride and phenylboronic acid. 130

### 4.1.3.1 Screening and Optimisation Reactions

The screening of the ligands (Table 4.2) revealed that $\mathbf{5 a}$ outperformed other monoPAPs significantly under the same conditions, as it was able to generate the biaryl product in $99 \%$ yield. Lower yields of $36 \%$ and $59 \%$ were obtained for 5 d and 5c respectively (Entries 1, 9 and 10). This may be due to their increased steric hindrance at the phosphazene core, which makes them bulkier than 5a. $\mathbf{9}$ performed well with $73 \%$ yield (Entry 11). The yield did drop significantly to $61 \%$ when the catalyst load was reduced to $0.5 \mathrm{~mol} \%$ (Entry 8 ). Interestingly,
if weaker bases such as $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ were used, the impact on the yield was enormous (Entry 4). This may be due to the inherent need to regenerate the [L-Pd] species through reductive elimination in the catalytic cycle. Due to the ligands intrinsic high basicity, weaker bases may not be able to sufficiently regenerate these. Another plausible reason is, that $\mathrm{CO}_{2}$ which is generated when metal carbonates are employed, can react with the free base PAP to form reversible PAP- $\mathrm{CO}_{2}$ adducts which are stable in contrast to $\mathrm{P} t \mathrm{Bu}_{3}-\mathrm{CO}_{2}$ adducts which require stabilization by a Lewis acid like BCF (tris(pentafluorophenyl)borane). ${ }^{219]}$ Solvent screening showed that coordinating solvents such as DME and THF slowed down the reaction, while toluene favored it (Entries 6 and 7). When compared under these optimized conditions, both SPhos as well as IMes yielded less product, with $16 \%$ and trace amounts only (Entries 12 and 13). However, it is reported that with $\mathrm{K}_{3} \mathrm{PO}_{4}$ as base and $\left[(\mathrm{MeCN})_{2} \mathrm{PdCl}_{2}\right]$ as precatalyst SPhos can couple with $90 \%$ yield in 5 h at $100^{\circ} \mathrm{C}$. ${ }^{[220]}$ IMes may also achieve these yields if microwave assisted or a $\left[\mathrm{Pd}(\pi-t \mathrm{Bu}-\mathrm{ind}) \mathrm{Cl}_{2}\right.$ precursor is employed. ${ }^{[220 \mid[22]]}$ The increased performance of IMes with $[\mathrm{Pd}(\pi-t \mathrm{Bu}-\mathrm{ind}) \mathrm{Cl}]_{2}$ as opposed to its cinnamyl equivalent can be attributed to a more stabilized transition state for the reductive elimination of the allyl moiety to form [L-Pd] as described earlier. Since these ligands are sensitive to air but can be converted to their $\mathrm{HBF}_{4}$ salts to allow their storage, it was of interest, if it was possible to employ these salts and in situ deprotonate them for usage as ligands. It turned out, that by including a simple deprotonation step by the base, followed by premixing with the Pd source $5 \mathrm{a}-\mathrm{HBF}_{4}$ performed similarly with a yield of $87 \%$ (Entry 5).

Table 4.2: Overview over the performed screening reactions for the SM coupling of toluyl chloride with phenylboronic acid.

| Entry | Ligand | Pd source ${ }^{[\mathrm{a}]}$ | Base | Solvent | Yield [\%] |

${ }^{\text {a }}$ DBA $=$ Bis-(dibenzylidenaceton)-palladium(0); cinn $=$ Palladium( $\pi$-cinnamyl)-chloride dimer; Allyl $=$ Allylpalladium(II) chloride dimer; Fu catalyst $=\operatorname{Bis}($ tri-tert-butylphosphine)palladium(0).
${ }^{\mathrm{b}} 0.5 \mathrm{~mol} \%$
${ }^{\text {c }}$ Room temperature
${ }^{d}$ Yield of $90 \%$ can be achieved by usage of $\mathrm{K}_{3} \mathrm{PO}_{4}$ as a base. ${ }^{[220]}$
${ }^{\mathrm{e}}$ Yield of $80 \%$ can be achieved in dioxane. ${ }^{[221]}$
${ }^{\mathrm{f}}$ Yield of $85 \%$ could be achieved with $\mathrm{Cs}_{2} \mathrm{CO}_{3}$. ${ }^{\text {.130] }}$ Reaction conditions: 1.0 eq. toluylchloride, 1.5 eq. phenylboronic acid, 2.0 eq. $\mathrm{NaOMe}, 4 \mathrm{~mol} \%$ ligand, $4 \mathrm{~mol} \%[\mathrm{Pd}], 8{ }^{\circ} \mathrm{C}$ for 16 h . Yields are isolated.

Next, the kinetic profile of this reaction was investigated by monitoring of the yield in timed intervals by removal of an aliquot from the reaction mixture and quantifying it by NMR spectroscopy with the help of an internal standard. From Figure 4.8 it can be deduced, that after an initial induction period, the highest activity is detected in the first 90 minutes of the reaction after which it begins to slow down until it has quantitatively proceeded after 4 h . The induction period can be rationalized as the time it takes to generate the active [L-Pd] species through reductive elimination of the cinnamyl moiety by the base and the subsequent oxidative addition of the aryl chloride, as described earlier. In fact, it has been proposed, that the initial generation of [L-Pd] may be the rate determining step. ${ }^{[209]}$ The conversion rate was determined at the amount of time it takes to convert the first $20 \%$ of substrate to the desired biaryl product. ${ }^{[222]}$ The conversion rate adjusted for the induction period was also determined, where the rate from the time where conversion is first detected is measured. This results in a rate of $0.63 \mathrm{~mol} / \mathrm{h}$ and $0.37 \mathrm{~mol} / \mathrm{h}$ for a concentration of 0.33 M and 0.033 m respectively. Adjusted for the induction period, this corresponds to a rate of $0.84 \mathrm{~mol} / \mathrm{h}$ and $0.70 \mathrm{~mol} / \mathrm{h}$.

Figure 4.8: Reaction rate of Suzuki-Miyaura coupling of 4-chlorotoluene and phenylboronic acid. Conditions: 1.0 eq. $\mathrm{ArCl}, 1.5$ eq. $\mathrm{PhB}(\mathrm{OH})_{2}, 2.0$ eq $\mathrm{NaOMe}, 4 \mathrm{~mol} \% \mathrm{5a}$, $2 \mathrm{~mol} \%[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}$. Yields are determined by integration and comparison of product peak to internal standard ( $1,3,5$-trimethoxybenzene).

### 4.1.3.2 Scope

Satisfied with these reaction conditions, the scope of this new ligand was investigated (Figure 4.9). Electron rich as well as electron poor arenes were coupled in excellent yields. Sterically demanding mesitylboronic acid was coupled with chloroanisole successfully with $78 \%$ yield. Chlorobenzenes with ortho-substitution were also coupled with both neutral and electron rich boronic acids. Electron poor arylchlorides with $p$-cyanido and trifluoromethyl groups also yielded good results. Mixtures of electron rich and electron poor substrates led to almost quantitative yields. Notably, it was possible to successfully couple a primary amino substituted aryl substrate, demonstrating the functional group tolerance of this system. While it must be conceded, that these ligands may not perform as well as some of the more specialized Buchwald ligands at very low catalyst loads, they are at least capable of delivering similar outputs to industry standards such as IMes, SPhos or the Fu Catalyst. ${ }^{[223]}$

Yields are isolated. [a] From Ar-Br.

### 4.1.4 Buchwald-Hartwig Amination

### 4.1.5 Screenings and Optimization Reactions

Similarly, it was of interest, if monoPAPs could be utilized as ligands for palladium catalyzed Buchwald-Hartwig amination reactions. The model reaction of 4-methylbromobenzene and morpholine was chosen to evaluate the reactivity of these ligands (Scheme 4.7).

Scheme 4.7: Screening of different PAP ligands in a Buchwald-HARTWIG amination reaction with $p$-toluyl bromide and morpholine. ${ }^{[130]}$
$\mathbf{5 a}, \mathbf{5 c}$ and $\mathbf{5 d}$ performed very well, achieving quantitative results in all three cases (Table 4.3).

Table 4.3: Overview over the screening conditions for the Buchwald-Hartwig amination of 4 -bromotoluene with morpholine.

${ }^{\text {a }}$ DBA $=$ Bis-(dibenzylidenaceton)-palladium $(0) ; \operatorname{cinn}=$ Palladium-( $\pi$-cinnamyl)-chloride dimer; Allyl $=$ Allylpalladium(II) chloride dimer; Fu catalyst $=$ Bis(tri-tertbutylphosphine)palladium(0).
${ }^{\mathrm{b}} 0.5 \mathrm{~mol} \%$
${ }^{c}$ From $\mathrm{Pd}(\mathrm{OAc})_{2}$ and $\mathrm{NaO} t \mathrm{Bu}$ in dioxane. ${ }^{[224]}$
${ }^{\mathrm{d}}$ From $(\mathrm{SIPr}) \mathrm{Pd}\left(\eta^{3}-1-\mathrm{Me}-\mathrm{allyl}\right) \mathrm{Cl}\left(\mathrm{SIPr}=N, N{ }^{\prime}-\operatorname{bis}(2,6-\right.$ diisopropylphenyl)-4,5-dihydroimidazol-2-ylidene) and LiHMDS in toluene. ${ }^{[225]}$
${ }^{\mathrm{e}}$ Isolated yield of $67 \%$ is reported in the literature. [223]
Reaction conditions: 1.0 eq. 4 -bromotoluene, 1.5 eq. morpholine, 2.0 eq. $\mathrm{KO} t \mathrm{Bu}, 4 \mathrm{~mol} \%$ ligand, $4 \mathrm{~mol} \%[\mathrm{Pd}]$, $80^{\circ} \mathrm{C}$ for 16 h . Yields are calculated using an internal standard of $1,3,5$-trimethoxybenzene and are obtained by integrating the product peaks compared to the standard.

As seen with the Suzuki-Miyaura reaction, when weaker bases were employed, the yields dropped significantly. The reaction proceeded well in toluene and worse in THF or DME. In
the case of $\mathbf{5 c}$ a reduction in catalyst load to $0.5 \mathrm{~mol} \%$ did not decrease the yield. Therefore, it was decided to focus on this ligand for subsequent reactions. 5c outperforms SPhos ( $78 \%$ yield at $4 \mathrm{~mol} \%$, literature value: $77 \%)^{[224]}$ and similar to optimized conditions for IMes $(19.2 \%$ yield at $4 \mathrm{~mol} \%$, literature value: $98 \%)^{[225]}$ and shows, at least for electron rich secondary amines, a comparable reactivity to Gessner's YPhos ligands. ${ }^{[72]}$ In analogue to the SUZUKiMiyaura coupling reaction, the kinetic profile of this reaction was investigated by removal of aliquots from the reaction mixture and determination of the yield using an internal standard (Figure 4.10). Notably, the conversion was completed in only ten minutes when utilized at high concentrations. No induction period was identified for this reaction, this may be due to the higher reactivity of aryl bromides compared to their chloride analogues. To better study the reaction kinetics, the concentration of substrates was lowered tenfold. This allowed the generation of a much better kinetic profile. With a conversion rate of about $0.04 \mathrm{~mol} / \mathrm{min}$ or $2.2 \mathrm{~mol} / \mathrm{h}$ the reaction proceeded much faster than the Suzuki-MiYaura coupling while operating at $1 / 8$ th the catalyst load.

Figure 4.10: Reaction rate of Buchwald-Hartwig amination of 4-bromotoluene and morpholine. Reaction conditions: 1.0 eq. 4 -bromotoluene, 1.5 eq. morpholine, 2.0 eq. $\mathrm{KO} t \mathrm{Bu}, 0.5 \mathrm{~mol} \%$ ligand, $0.25 \mathrm{~mol} \%[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}, 80^{\circ} \mathrm{C}$ for 16 h . Yields are calculated using an internal standard of $1,3,5$-trimethoxybenzene.

### 4.1.5.1 Scope

To explore the scope of this reaction several compounds were prepared, as evidenced by Figure 4.11. Utilizing $5 \mathbf{c}$ at a catalyst load of $0.5 \mathrm{~mol} \%$ electron rich and sterically demanding bromoarenes with various anilines were efficiently coupled. The employment of electron poor arenes is accompanied by a large decrease in the yield. Notably, if the aniline is electron poor,
the coupling proceeds satisfactorily with sterically demanding, as well as electron rich arenes. Secondary amines couple efficiently but need, in the case of pyrrolidine, a higher catalyst load. With this higher catalyst load, it was also possible to couple aryl chlorides with electron rich anilines with excellent yields, while the coupling with pyrrolidine proceeded in only $27 \%$. Coupling reactions with primary amines such as $n$-butyl amine were also performed, but did not lead selectively to the desired products. For $\mathbf{5 a}$ the product could only be isolated in trace amounts. For $5 \mathbf{c}$ a satisfactory yield of $69 \%$ could be achieved, however a significant amount of homocoupling (about $20 \%$ ) could also be detected. The reason for this better performance of $5 \mathbf{c}$ compared to 5 a may be attributed to agostic interactions between the ligand backbone and the oxidative addition product [ $\mathrm{L}-\mathrm{Pd}-(\mathrm{Ar}) \mathrm{Br}]$.

Figure 4.11: Scope of palladium catalyzed Buchwald-Hartwig amination. Yields are isolated. Yields in brackets correspond to the yield from the aryl chloride. Reaction conditions: 1.0 eq. $\mathrm{ArBr}, 1.5$ eq. amine, 2.0 eq. $\mathrm{KO} t \mathrm{Bu}, 0.5 \mathrm{~mol} \% \mathbf{5 c}, 0.25 \mathrm{~mol} \%$ $\left[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}_{2}\right.$. Yields are isolated. [a] $4 \mathrm{~mol} \% \mathbf{5 d}, 2 \mathrm{~mol} \%[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}$. [b] NMR yield.

### 4.1.6 Gold complexes

Spurred by a recent surge in interest of the scientific community in gold catalyzed coupling reactions, it was decided, that the usage of PAPs in these transformations should be investigated. Of particular interest were cationic $\mathrm{Au}(\mathrm{I})$-complexes which can be used for coupling reactions of alkynes, alkenes and allenes with various nucleophiles. ${ }^{[226[227]}$ GESSNER and DIELMANN report the hydroamination of acetylenes with low catalyst loads for YPhos and IAP ligands, respectively. ${ }^{[60[128]}$ BERTRAND reports the cyclic-alkylaminocarbene (CAAC) supported addition of ammonia to allenes and alkynes ${ }^{[228]}$ while ESPINES reports the usages of nitrogen acyclic carbenes (NAC) for hydroarylation reactions. ${ }^{[229]}$ ZHANG reports a ligand design concept for ligand-directed anti-nucleophilic attacks of alkynes with catalyst loads as low as the ppm level. ${ }^{230}$ These ligands utilize BUCHWALD-type biaryl directing groups to allow for stabilizing arene interactions. Gessner's and Dielmann's ligands utilize these interactions too. An overview over different ligands employed in gold catalysis is given in Figure 4.12 .

Figure 4.12: Various ligands employed in gold catalysis.

### 4.1.7 Hydroamination of Acetylenes

To explore the ability of PAPs to catalyze the hydroamination of acetylenes a model reaction of phenylacetylene and aniline was selected. The ligand $(\mathrm{dma}) \mathrm{P}_{3} \mathrm{P}(\mathbf{7 a})$ was chosen as a highly electron rich example. The gold complex of $\mathbf{7 a}, \mathbf{3 4 a}$, was isolated and added to the reaction mixture together with sodium-tetrakis-[3,5-bis-(trifluormethyl)-phenyl]-borate $\left(\mathrm{NaBAF}^{\mathrm{F}}\right)$ as a chloride scavenger. ${ }^{[230]}$ The yield was determined by direct integration of the acetylene proton to the methyl group of the product (Scheme 4.8).

Scheme 4.8: Overview over the performed hydroaminations of phenylacetylene with 7a. Reaction conditions: 1.0 eq. phenylacetylene, 1.5 eq. aniline, $0.5 \mathrm{~mol} \% \mathbf{3 4 a}, 0.5 \mathrm{~mol} \%$ $\mathrm{NaBAr}{ }^{\mathrm{F}}$. Yield determined by direct integration of the acetylene proton to the methyl group of the product.

This reaction shows the potential for this type of coupling as it proceeds, in the case of the coupling of phenylacetylene and aniline, in quantitative yields. For electron rich as well as electron poor anilines, the yield decreases. Notably, the reaction may also be performed solvent free without loss in performance.

### 4.2 Summary

It was successfully demonstrated, that easily synthesized monophosphazenyl phosphines 5a5d could be employed as ligands in transition metal catalyzed cross coupling reactions such as the palladium catalyzed Suzuki-Miyaura coupling and the Buchwald-Hartwig amination. These sterically demanding and extremely electron rich phosphines with TEPs of around 2040 can be used to form an air stable precatalyst of the type $\left[\operatorname{PAP}-\operatorname{Pd}\left(\eta^{3}-\operatorname{cinn}\right) \mathrm{Cl}\right]$ or as $\mathrm{PAP}-\mathrm{HBF}_{4}$ salts that can be deprotonated and mixed with the palladium source. The applicability of these ligands was shown by preparation of a relevant substrate scope, showcasing its strengths and limitations in both the Suzuki-Miyaura coupling as well as the Buchwald-Hartwig amination. Additionally, the abilities of 7a in gold catalyzed alkyne hydroaminations was explored in a preliminary study.

## 5 Organocatalytic Applications of PAP Superbases

### 5.1 Results and Discussion

### 5.1.1 N -Alkylation of Indoles

The important role of heterocycles, especially $N$-alkylated indoles and pyrroles, has been established by the scientific community in particular in the field of pharmacologic research. [231] They can be utilized in a wide array of pathophysiological conditions such as inflammation, depression, and cancer. ${ }^{[232-235]}$ As such, the synthesis of these compounds is of interest. The alkylation can be achieved through several means. Base promoted alkylation by the addition of stochiometric or several equivalents of an inorganic base such as cesium carbonate yields the desired product. ${ }^{[236]}$ Other methods include the use of $n$ - BuLi in THF ${ }^{[237]}$ or KOH in ionic liquids. ${ }^{[238]}$ Recently, the catalytic $N$-alkylation of indoles by $\mathrm{KO} t \mathrm{Bu}$ in solvent free conditions was reported. ${ }^{[239]}$ The catalytic $N$-alkylation of indoles by monomeric phosphates has also been reported. ${ }^{[240]}$ Most impressively, the cyclopropenimine superbase catalyzed $N$-Alkylation of indoles was reported as a completely metal free alternative by Lambert et al. [241]

### 5.1.2 Alkylation of Indoles with PAP

Spurred by this discovery of Lambert et al., the applicability of PAPs for these base catalyzed Michael reactions came into focus. The model reaction of indole with $(E)$-but-2-enenitrile was chosen with bases 5a and $\mathbf{7 a}$ at $2.5 \mathrm{~mol} \%$ in THF at $60^{\circ} \mathrm{C}$ (Scheme 5.1). It is evident, that the base strength is imperative for this transformation, as the weaker base 5a showed no reaction. This is in line with Lambert's discoveries, as his weaker mono cyclopropeneimine bases did not react as well. ${ }^{241]}$ Therefore, the focus was put on trisPAPs $\mathbf{7 a}$ and $\mathbf{7 b}$ which showed promising results.

Scheme 5.1: Screening of different PAP ligands and cyclopropeneimine ligands for the N alkylation of indole with ( $E$ )-but-2-enenitrile. ${ }^{[85[24]}$

Next, the influence of different catalyst loads on the reaction was investigated. The reaction was performed with catalyst loads of 1 to $20 \mathrm{~mol} \%$ for $\mathbf{7 a}$ and $\mathbf{7 b}$ (Table 5.1).

Table 5.1: Screening of the influence of the catalyst loading on the $N$-alkylation of indoles with $\mathbf{7 a}$ and $\mathbf{7 b}$.

| Catalyst load [mol\%] | Base | Yield [\%] | Base | Yield [\%] |
| :--- | :--- | :--- | :--- | :--- |
| 20 | $\mathbf{7 a}$ | 55 | 7b | 41 |
| 10 | $\mathbf{7 a}$ | 76 | 7b | 62 |
| 5 | $\mathbf{7 a}$ | 84 | 7b | 75 |
| 2.5 | $\mathbf{7 a}$ | 87 | 7b | 94 |
| 1 | $\mathbf{7 a}$ | 10 | 7b | $29(51)^{[\mathrm{bb}}$ |

${ }^{\text {a }}$ Reaction conditions: 1.0 eq. alkene, 1.5 eq. indole, THF, RT, 16 h . Yields are determined with the help of an internal standard of $1,3,5$-trimethoxybenzene by integration of the methyl group of the product to the internal standard.
${ }^{\mathrm{b}} 60{ }^{\circ} \mathrm{C}$

A proposed mechanism for this reaction is shown in Scheme 5.2. The reaction is initiated by deprotonation of the indole by the superbase which generates protonated PAP and an anionic indole (I). This anionic species may attack the alkene (II) to form a carbanionic intermediate (III). This intermediate reacts with another molecule of indole to form the product and another anionic indole (IV). It is necessary for this reaction, that the superbase is strong enough to deprotonate the NH functionality of the indole $\left(\mathrm{p} K_{a}=32.6 \text { in } \mathrm{MeCN}\right)^{[242]}$. Additionally, the carbanionic intermediate (III) needs to be strong enough to deprotonate another equivalent of indole. Table 5.1 shows, that a lower catalyst load yields (up to a point) to a higher yield. This may be attributed to an increase in side reactions between the superbase and the alkene, like the nucleophilic attack on the alkene by the base (V). This could be confirmed by the deliberate reaction between $\mathbf{7 a}$ and acrylnitrile, which yielded the adduct.

Scheme 5.2: Proposed catalytic cycle for the $N$-alkylation of indoles catalyzed by PAP bases.

Additionally, according to the proposed catalytic cycle, the superbase does not react with the alkene directly. To further support this hypothesis, another experiment was performed. By the addition of 5 mL of 'wet' hexane ( $100 \mathrm{ppm} \mathrm{H}_{2} \mathrm{O}$ ) the superbase was quantitatively protonated which eliminates any possibility of a reaction between base and alkene. Instead, the indole is deprotonated by the resulting $\mathrm{OH}^{-}$anion. This succeeded with a yield of $88 \%$.

The kinetic profile of this reaction was investigated by monitoring of the yield in timed intervals by removing an aliquot from the reaction mixture and quantifying it by NMR spectroscopy with the help of an internal standard (Figure 5.1).

Figure 5.1: Kinetics of $N$-alkylation of indoles. Reaction conditions: 1.0 eq. alkene, 1.5 eq. indole, THF, RT, 16h. Yields are determined with the help of an internal standard of $1,3,5$-trimethoxybenzene by integration of the methyl group of the product to the internal standard.

### 5.1.2.1 Scope

Satisfied with these reaction conditions, the scope of this reaction was explored. A small array of electron poor alkenes was coupled with electron rich and electron poor indoles (Figure 5.2).

Figure 5.2: Scope of $N$-alkylation of indoles. Reaction conditions: 1.0 eq. alkene, 1.5 eq. indole, THF, $60^{\circ} \mathrm{C}$ or RT, 16 h . Yields are determined with the help of an internal standard of $1,3,5$-trimethoxybenzene by integration of the methyl group of the product to the internal standard.

This screening demonstrates, that electron rich and electron poor indoles couple efficiently with electron poor Michael acceptors. Unsubstituted acrylamide requires additional heating to $60^{\circ} \mathrm{C}$ to react efficiently with indoles. Trisubstituted ethene-1,1,2-tricarbonitrile did not react, presumably because its corresponding carbanion is unable to deprotonate the starting indole.

### 5.1.3 Organic Bases as Catalysts for the Coupling of $\mathrm{CO}_{2}$ and Epoxides

### 5.1.3.1 $\mathrm{CO}_{2}$ adducts of Organic Bases

Carbon dioxide is a valuable and easily accessible $\mathrm{C}_{1}$ building block that can be utilized in chemical synthesis. $\mathrm{CO}_{2}$ can form stable adducts with a variety of non-protic organic bases. Already in 1966 Matthews ${ }^{[243]}$ et al. described the formation of a phosphorus ylide$\mathrm{CO}_{2}$ adduct (Figure [5.3) while Kuhn ${ }^{[244]}$ et al. describes the formation of a stable NHC$\mathrm{CO}_{2}$ adduct. Villiers et al. describes the successful isolation and structure determination of TBD- $\mathrm{CO}_{2}\left(\mathrm{TBD}=1,5,7\right.$-triazabicyclo[4.4.0]dec-5-en). ${ }^{[245]}$ In recent years, Dielmann et al. describes the synthesis of bis and trisIAP- $\mathrm{CO}_{2}$ adducts. [161]246]

Matthews 1966

Kuhn 1999

Villiers 2010

Dielmann 2016

Figure 5.3: Different adducts of organic bases with $\mathrm{CO}_{2}$.

These compounds have been investigated toward their thermal stability by various groups. Dielmann was able to establish a clear correlation between the decomposition temperature of his IAP $-\mathrm{CO}_{2}$ adducts and the TEP. ${ }^{[161 \mid 246]}$ The lower the TEP and the higher the electron donating ability of the base, the higher the decomposition temperature. Louie et al. reports similar findings for NHC- $\mathrm{CO}_{2}$ adducts. ${ }^{[247]}$ They also argue, that an increased steric bulk on the $N$-substituent of the NHC contributes to the stability of the adduct. JI et al. reports a linear correlation of the basicity of NHCs and the thermal stability of $\mathrm{NHC}-\mathrm{CO}_{2}$ adducts. ${ }^{[248]}$ Dielmann makes use of this by the synthesis of photoswitchable $N$-heterocyclic imines (NHI) with a photochromic dithienylethene unit which undergoes reversible cycloisomerisation by irradiation with UV light which is accompanied by a large decrease of basicity by 8.7 units. ${ }^{[249]}$ The ring closed base isomer releases the $\mathrm{CO}_{2}$ and therefore enables light controlled capture and release of $\mathrm{CO}_{2}$.

### 5.1.3.2 $\mathrm{CO}_{2}$ Adducts of PAP

Spurred by these discoveries, the availability of PAP- $\mathrm{CO}_{2}$ adducts was investigated. PAPs $\mathbf{5 a}-\mathbf{5 d}, \mathbf{6 a}-\mathbf{6 b}$ and $\mathbf{7 a - 7 b}$ were reacted with $\mathrm{CO}_{2}$. The findings of these experiments mostly correlate with the aforementioned literature. MonoPAP adducts 39a-39d were unstable at room temperature and decomposed almost immediately. BisPAP adducts 40a-40b as well as trisPAP adducts 41a-41b were stable at room temperature and only decarboxylated after heating to $80{ }^{\circ} \mathrm{C}$ over 30 minutes. An overview over the ${ }^{13} \mathrm{C}$-NMR chemical shifts, the ${ }^{1} J_{(P, C)}$ coupling constants as well as the $\tilde{v}\left(\mathrm{CO}_{2}\right)$ IR band is given in Table 5.2 as well as the structures in Figure 5.4

${ }^{\text {a }}$ Measured in $\mathrm{C}_{6} \mathrm{D}_{6}(75 \mathrm{MHz})$.
${ }^{\mathrm{b}}$ Measured via ATR-IR spectroscopy of the neat substance.

From this table, a clear correspondence between the basicity of the parent PAP and the ${ }^{1} J_{(P, C)}$ coupling constant can be determined. The $\tilde{v}\left(\mathrm{CO}_{2}\right)$ IR band behaves similarly. Thermogravimetric analysis to determine the exact decomposition temperature of these adducts has been performed, but did not lead to conclusive results and are therefore not included herein. It should be noted, that after heating, the parent PAP is regenerated and no decomposition or metathesis products could be detected by ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy.

### 5.1.3.3 Crystal Structure of PAP-CO $\mathrm{CO}_{2}$ adducts.

Single crystals suitable for XRD analysis were obtained for 40a (Figure 5.5), 41a (Figure 5.6) and 41b (Figure 5.7) by slow cooling of a saturated solution in pentane to $-30^{\circ} \mathrm{C}$. The P1-C1 bond length of trisPAPs 41a and 41b of $1.88 \AA$ are comparable to the bond lengths of Dielmann's trisIAP. ${ }^{[246]}$ The O2-C1-O1 bond angle of the $\mathrm{CO}_{2}$ fragment of $128.5^{\circ}$ is also almost exactly the same. ${ }^{[246]}$ BisPAP 40a possesses a P1-C1 bond length of $1.90 \AA$ which is slightly longer than the length of the P1-C1 bond in bisIAP with $1.88 \AA$. The O2-C1-O1 bond angle of the $\mathrm{CO}_{2}$ fragment of $129.5^{\circ}$ is very similar to the $129.6^{\circ}$ in bisIAP. ${ }^{249]}$ VILLIER's TBD- $\mathrm{CO}_{2}$ adduct also possesses a similar bond angle of $128.6^{\circ} .{ }^{[245]}$

Figure 5.5: Molecular structure of 40a. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles $\left[{ }^{\circ}\right]$ : C1O1 1.234(6), C1-O2 1.237(5), C1-P1 1.900(4), N1-P1 1.592(4), N5-P1 1.601(3), N1-P2 1.557(4), N5-P3 1.557(3); O2-C1-O1 129.5.

Figure 5.6: Molecular structure of 41a. Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity. Notable bond lengths $[\AA]$ and angles $\left[{ }^{\circ}\right]$ : C1O1 1.255(3), C1-O2 1.239(3), C1-P1 1.885(3), N5-P1 1.613(2), N1-P1 1.605(2), N1-P2 1.555(2), N5-P3 1.561(2); O2-C1-O1 128.7.

Notable bond lengths $[\AA]$ and angles [ ${ }^{\circ}$ !: C1-O1 1.244(3), C1-O2 1.245(3), C1-P1 1.882(2), N1-P1 1.6171(18), N9-P1 1.6111(18), N5-P1 1.6090(17), N1-P2 1.5562(18), N5-P3 1.5513(18).

### 5.1.3.4 Catalytic Applications of PAP- $\mathrm{CO}_{2}$ Adducts.

The catalytic potential of organobase- $\mathrm{CO}_{2}$ adducts for the carboxylation of epoxides has been demonstrated in the past. Lu et al. demonstrated in 2008 the NHC-CO ${ }_{2}$ catalyzed carboxylation of propylene oxides with excellent yields at $\mathrm{CO}_{2}$ pressures of 20 bar at $120{ }^{\circ} \mathrm{C}$ (Figure [5.8). ${ }^{[135]}$ Mechanistically, they propose a nucleophilic attack of the zwitterionic NHC- $-\mathrm{CO}_{2}$ as the first step. In 2015 the same group reported the cyclic addition of $\mathrm{CO}_{2}$ with phosphorus ylide- $\mathrm{CO}_{2}$ adducts. ${ }^{[250]}$ They propose a different mechanism, where first the P -ylide- $\mathrm{CO}_{2}$ adduct activates a free $\mathrm{CO}_{2}$, forming a zwitterionic species which is more nucleophilic than the P -ylide- $\mathrm{CO}_{2}$ acetate anion because of reduced steric hindrance. Based on the work of Dufaud, the group of Martinez utilized fluoroazaphosphatranes as effective catalysts for the carboxylation of epoxides. ${ }^{[251][252]}$ They propose a coordination of the oxygen atom of the epoxide to the azaphosphatrane which enables a nucleophilic attack of the chloride anion to open the epoxide. Next, a $\mathrm{CO}_{2}$ molecule inserts into the $\mathrm{P}-\mathrm{NCH}_{2} \mathrm{CH}_{2}$ bond of the azaphosphatrane. The cyclic carbonate is generated by nucleophilic attack of the open epoxide on this species, which regenerates the fluoroazaphosphatrane. Schwesinger's phosphazene bases have been successfully utilized in the catalytic hydrosilylation of carbon dioxide. [253]

Figure 5.8: Examples of organobases utilized for the carboxylation of epoxides.

These findings prompted an investigation in the applicability of phosphazenyl phosphine (PAP) and carbodiphosphorane (CDP) bases in these transformations. The following results have been prepared as an internal group cooperation with Igor Martin, who investigated the applicability of CDPs, and MORTEN Dittmar, who performed the screenings (Table [5.3). [254] This section will focus only on the performance of PAP bases. For an initial screening of bases the coupling of butylene oxide with $\mathrm{CO}_{2}$ was selected (Scheme 5.3).

Scheme 5.3: Screening reaction for the coupling of butylene oxide with $\mathrm{CO}_{2}$ with different PAP. Conditions: 20 mmol butylene oxide, 40 bar $\mathrm{CO}_{2}$, yields determined by GC FID, no oligomers were detected by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy.

All reactions were performed by Morten Dittmar in an internal group cooperation. Bases were provided by Sebastian Wagner. ${ }^{[254]}$
${ }^{\text {a }}$ Conditions: 20 mmol butylene oxide, 40 bar $\mathrm{CO}_{2}$, yields determined by GC FID, no oligomers were detected by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy.

Except for 9, all monoPAP bases were able to catalyze the formation of butylene carbonate (Table 5.3). The lack of reactivity of $\mathbf{9}$ most likely stems from its lack of basicity and nucleophilicity, which hinders the formation of $\mathrm{CO}_{2}$ adducts as described earlier. ${ }^{[248]} 5$ a performed well, even at low catalyst loadings of $0.1 \mathrm{~mol} \%$. The lack of reactivity at $50{ }^{\circ} \mathrm{C}$ compared to $120{ }^{\circ} \mathrm{C}$ may be due to the kinetic barrier of the epoxide opening. Bulkier 5 c and 5 d performed worse than 5 a and $\mathbf{5 b}$ as they are less nucleophilic. 7a could not be employed as its free base form for this reaction as it underwent rapid and exothermic polymerization with the epoxide. Therefore, the $\mathrm{CO}_{2}$ adduct 41a was isolated prior to the reaction. This makes it unlikely, that the mechanism for this transformation undergoes a nucleophilic attack of the superbase on the epoxide. ${ }^{31} \mathrm{P}$-NMR spectra after the reaction show protonated $\mathbf{7 a}-\mathrm{H}^{+}$ as the only species, which leads to the assumption, that, through trace moisture from the epoxide, the base gets protonated and a highly reactive unsolvated $\mathrm{HCO}_{3}^{-}$anion is formed. This is probable, taking into account the extreme moisture sensitivity of $\mathbf{7 a}$ and the limited availability of drying agents for epoxides. ${ }^{[135[255]}$ The reduced yield of 41a compared to 5 a coincides with the observation of LU et al. that higher thermal stability corresponds to lower catalytic activity. ${ }^{[135]}$ Similar observations were made, when hexaphenylcarbodiphosphorane $\left(\mathrm{CDP}-\mathrm{Ph}_{6}\right)$ was employed. After the reaction only protonated $\mathrm{CDP}-\mathrm{H}^{+}$was detected by ${ }^{31} \mathrm{P}-$ NMR and, after addition of additional substrate, the reaction would continue confirming the role of the bicarbonate anion. ${ }^{[254]}$ Taking these findings into account, the following catalytic cycle is proposed, derived from one previously reported by PARK et al. (Scheme [5.4). ${ }^{[256]}$ First, the bicarbonate anion is generated by reaction of trace moisture with the PAP and $\mathrm{CO}_{2}(\mathrm{I})$. The bicarbonate anion then attacks the epoxide, leading to a ring opening (II). This adduct reacts with a second molecule of $\mathrm{CO}_{2}$ (III). Through an intramolecular nucleophilic attack, the cyclic carbonate is liberated, and the bicarbonate anion regenerated (IV). An alternative mechanism, first proposed by Suresh et al., is initiated by the generation of the Base- $\mathrm{CO}_{2}$ adduct (Ib). ${ }^{[257]}$ This adduct may open the epoxide via nucleophilic attack (IIb). The ring is closed by an intramolecular nucleophilic attack on the carbonyl carbon atom by the alkoxide (IIIb). This liberates the cyclic carbonate and the free base (IVb).

Scheme 5.4: Proposed catalytic cycle for the carboxylation of epoxides with PAP bases (left) and alternative cycle (right).

### 5.2 Summary

It was shown, that highly basic trisPAP can act as efficient, completely metal free catalysts for the alkylation of indoles with low catalyst loadings. These reactions were performed under mild conditions, in most cases in only two hours. The scope of this reaction ranges from electron rich to electron poor indoles with challenging acrylamide substrates. Furthermore, the synthesis, stability, characteristics, and applicability of $\mathrm{PAP}-\mathrm{CO}_{2}$ adducts was investigated. These adducts can be categorized according to their basicity, which is manifested in the ${ }^{1} J_{(P, C)}$ coupling constant of the central phosphorus atom and the $\mathrm{CO}_{2}$ carbon atom as well as in the $\tilde{v}\left(\mathrm{CO}_{2}\right)$ vibrational mode. Single crystals of many of these adducts were obtained and described. PAP were employed as efficient catalysts in the coupling of butylene oxide with $\mathrm{CO}_{2}$ in low catalysts loadings. The mechanism of this reaction was investigated, and a catalytic cycle was proposed.

## 6 Summary and Outlook

### 6.1 Summary

Trisphosphazenyl phosphines (trisPAP), first introduced by S. UllRICH from our group, are the strongest uncharged metal free bases known in Chemistry. ${ }^{[85[86]}$ With these compounds in hand, the application potential in a variety of transition metal and organocatalytic transformations were of interest. The question if it was possible to substitute one or two of the phosphazenyl groups by alkyl groups and the influence this would have was also of interest (Figure 6.1). These new compounds should be investigated towards their basicity, nucleophilicity, chemical stability, donor capabilities and coordination behavior.

Figure 6.1: Overview over various phosphazenyl phosphine compounds.

### 6.1.1 Synthesis and Characterisation of PAP

The topical superbase class of phosphazenyl phosphines (PAPs) was extended to include several novel mono- and bisphosphazenyl phosphines. They were synthesized from tertiary $\mathrm{P}(\mathrm{III})$-amides or a tertiary phosphine by Staudinger reaction with $\mathrm{TMSN}_{3}$ (Scheme 6.1). By reaction of these $N$-silyl $\mathrm{P}(\mathrm{V})$-imides with $\mathrm{PCl}_{3}$ and subsequent elimination of TMSCl, monophosphazenyl phosphorus dichlorides $\mathbf{4 a}-4 \mathrm{~d}$ were generated. At this step, a variety of different functional groups may be added via substitution. However, $t$-butyl groups have proven to be the most selective. MonoPAPs 5a-5f were synthesized in this manner.

Scheme 6.1: Synthesis of monoPAP 5a to $\mathbf{5 f}$.

Additionally, phosphoramidite 9 was synthesized as a potentially better $\pi$-acceptor ligand in contrast to the overwhelmingly high $\sigma$-donor character of $\mathbf{5 a - 5 f}$. The synthesis involved the reaction of 2-6-diisopropylphenol (dippOH) with $\mathrm{PCl}_{3}$ and subsequent reaction with $\mathbf{2 a}$ - Li to yield 9 (Scheme 6.2).

Scheme 6.2: Synthesis of monoPAP 9 from 8 and $\mathrm{PCl}_{3}$.

Additionally, the first amino substituted bisPAPs 6a-6b were synthesized by reaction of the corresponding phosphazenes $\mathbf{2 a} \mathbf{- 2 b}$ with $n$ - BuLi and subsequent reaction with $t-\mathrm{BuPCl}_{2}$ (Scheme 6.3).

$$
\begin{aligned}
& \begin{array}{lllll}
\mathrm{R}=\mathrm{NMe}_{2} & \mathbf{2 a} & \text { quant. } & \mathbf{6 a} & 70 \% \\
\mathrm{R}=\mathrm{pyrr} & \mathbf{2 b} & \text { quant. } & \mathbf{6 b} & 75 \%
\end{array}
\end{aligned}
$$

Scheme 6.3: Synthesis of bisPAP 6a and $\mathbf{6 b}$.

BisPAP 13 was designed with a biaryl backbone that resembles the famous Buchwald ligands.

It was synthesized by reaction of bromobiaryl 10 with $n$ - BuLi and $\mathrm{P}\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{Cl}$ to yield 11 (Scheme 6.4). 12 is liberated via cleavage of the $\mathrm{P}-\mathrm{N}$ bonds with HCl . Subsequent reaction with 2a-Li generates the biaryl substituted bisPAP 13.

Scheme 6.4: Synthesis of $\mathbf{1 3}$ by reaction of $\mathbf{2 a - L i}$ with $\mathbf{1 2}$.

In order to evaluate the nucleophilicity of these new PAP ligands, they were reacted with an excess of dried ethyl iodide. There are two possible mechanistic paths for this reaction, either the PAP reacts as a nucleophile and forms a P-ethylated phosphonium PAP via $S_{N} 2$ reaction or the PAP reacts as a base in a $E_{2}$ reaction and is protonated (Scheme 6.5).

Scheme 6.5: Evaluation of the nucleophilicity of different PAP bases.

Through quantitative ${ }^{31} \mathrm{P}$-NMR measurements, it was possible to determine the ratio of PAP-Et to PAP- $\mathrm{H}^{+}$by integration of the corresponding $\mathrm{P}(\mathrm{III})$ or $\mathrm{P}(\mathrm{V})$ signals and therefore measure the nucleophilicity of these PAPs. The electronic properties of the ligands were determined by the Tolman electronic parameter (TEP) as well as the ${ }^{1} J_{(P, S e)}$ coupling constant of the corresponding phosphazenylphosphine selenides. It was found, that monoPAP possess TEPs of $2040 \pm 2$ which is lower (electron richer) than popular NHCs such as IMes $(2050.5)^{[158]}$ and $\operatorname{ImNMe}_{2}(2054.1)^{[158]}$ or phosphines like $\mathrm{P}^{[10} \mathrm{Bu}_{3}(2056.1)^{[90]}$ and similar to ylidenaminophosphines (IAP) ${ }^{[81[159]}$ (Figure 6.2) of Dielmann and ylide functionalized phosphines (YPhos) ${ }^{[59][71 \mid 73]}$ of Gessner. Structural parameters of these $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes were investigated by XRD analyses.

Figure 6.2: TEP values of the nickel tricarbonyl complexes of PAP and various other ligands. Exact values for these examples are given in Table 3.3.

The basicity of PAPs was determined by competition experiments with a comparable base of known $\mathrm{p} K_{B H^{+}}$value. Additionally, the gas phase basicity ( GB ), proton affinity ( PA ) and solution basicity was calculated using DFT methods. MonoPAPs 5a-5f all exhibit similar $\mathrm{p} K_{B H^{+}}(\mathrm{MeCN})$ values of $25 \pm 1$. As expected, $\mathbf{6 a}$ and $\mathbf{6 b}$ are stronger than their monoPAP analogues $\mathbf{5 a}$ and $\mathbf{5 b}$ and weaker than their trisPAP analogues $\mathbf{7 a}$ and $\mathbf{7 b}$. This is further supported by the calculated $\mathrm{p} K_{B H^{+}}$values, which match the experimental values. This trend can also be seen in the GB and PA of these compounds. For the steric properties of PAPs the cone and solid angles as well as the buried volumes have been calculated. Mono and bisPAPs possess very high cone angles of around $200^{\circ}$, which surpasses $\mathrm{P} t \mathrm{Bu}_{3}\left(182^{\circ}\right)^{[89]}$ and lies in the same range as GESSNER's YPhos $\left(199^{\circ}\right)$. 60$]$ The buried volumes follow a similar trend and range from $44-55 \%$. For a closer investigation into the nature of the donor capabilities, a series of calculations was performed to determine the strength of $\sigma$-donation and $\pi$-acceptance by the change of Mulliken charges. This study established PAPs as strong $\sigma$-donors. Their $\pi$ acceptance character is increased by the introduction of alkyl groups on the central phosphorus atom, but is still very low. It can be said, that each added phosphazenyl group (by replacing a $t$-butyl group) increases the $\sigma$-donor and decreases the $\pi$-acceptor character of the ligand.

### 6.1.2 PAP as Ligands in Transition Metal Catalysis

The nature of PAPs as ligands in transition metal catalysis was investigated by reaction with a variety of palladium sources. The resulting palladium complexes were analyzed via XRD and compared to similar ligands (Figure 6.3).

Figure 6.3: Molecular structure of $\left[\mathrm{Pd}(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2^{-}}\left(\eta^{3}-\operatorname{cinn}\right) \mathrm{Cl}\right] \quad$ (left, 35a) and $\left[\mathrm{Pd}\left((\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}\right)_{2}\right](\mathbf{3 7}$, right). Ellipsoids are set at $50 \%$ probability. Hydrogen atoms have been omitted for clarity.

In order to test these ligands with respect to their applicability in cross coupling reactions, they were employed in palladium catalyzed SUZUKi-MiYAURA coupling reaction of a variety of boronic acids with aryl chlorides (Scheme 6.6). After optimization of the reaction conditions and an investigation of the kinetic reaction profile, an extensive scope of aryl-aryl' coupling products was established. It was possible to couple electron rich and neutral boronic acids with electron poor, electron rich and sterically demanding aryl chlorides with catalyst loads of $4 \mathrm{~mol} \%$. The system was also successfully used for the coupling of heterocyclic aryl chlorides and showed tolerance to a variety of functional groups.

Scheme 6.6: Palladium catalyzed Suzuki-Miyaura couplings. Reaction conditions: 1.0 eq. $\mathrm{ArCl}, 1.5$ eq. $\mathrm{ArB}(\mathrm{OH})_{2}, 2.0$ eq. $\mathrm{NaOMe}, 4 \mathrm{~mol} \% \mathbf{5 a}, 2 \mathrm{~mol} \%\left[\operatorname{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}_{2}\right.$. For scope see Figure 4.9 in Chapter 4.

A similar approach was taken in the investigation in the applicability of palladium catalyzed Buchwald-Hartwig aminations with PAPs 5c and 5d (Scheme 6.7). It was possible to couple electron rich as well as electron neutral anilines to aryl bromides with low catalyst loads of $0.5 \mathrm{~mol} \%$. However, the usage of electron poor aryl bromides impeded the yield tremendously. Sterically demanding anilines like mesitylaniline were efficiently coupled to 1-bromo-4-methylbenzene in $91 \%$ yield. The C-N coupling of secondary electron rich amines like morpholine yielded almost quantitative results.

Scheme 6.7: Palladium catalyzed Buchwald-Hartwig amination. Reaction conditions: 1.0 eq. $\mathrm{ArBr}, 1.5$ eq. amine, 2.0 eq. $\mathrm{KO} t \mathrm{Bu}, 0.5 \mathrm{~mol} \% \mathbf{5 c}$ or $\mathbf{5 d}, 0.25 \mathrm{~mol} \%$ $\left[\operatorname{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}_{2}\right.$. For scope see Figure 4.11 in Chapter 4.

### 6.1.3 Organocatalytic Applications of PAP

The superbase catalyzed $N$-alkylation of indoles was explored by the reaction of indole with E-but-2-enenitrile with various PAP catalysts. After an initial screening of reaction conditions and an investigation into the kinetic profile of the reaction a suitable reaction protocol was established (Scheme 6.8). With catalyst loads of $2.5 \mathrm{~mol} \%, 7 \mathbf{b}$ was able to efficiently catalyze the $N$-alkylation of electron rich as well as electron poor indoles with a variety of Michael acceptors such as acrylamide and methyl acrylate with good to excellent yields.

Scheme 6.8: PAP catalyzed $N$-alkylation of indoles. Reaction conditions: 1.0 eq. alkene, 1.5 eq. indole, THF, RT, 16h. For scope see Figure 5.2 in Chapter 5.

The reactivity, stability, and structure of $\mathrm{PAP}-\mathrm{CO}_{2}$ adducts was investigated and several XRD structures were obtained. It was possible to establish a distinct correlation between the basicity of the parent PAP and the ${ }^{1} J_{(P, C)}$ coupling constant of the adduct. These findings prompted an investigation into the catalytic applications of such PAP- $\mathrm{CO}_{2}$ adducts for the carboxylation of epoxides (Scheme 6.9). Through screening of different P-bases (PAP) and C-bases (carbodiphosphoranes, CDP) in cooperation with Morten Dittmar and Igor MARTIN a set of conditions could be established. Investigations into the mechanistic aspects revealed a high probability of the involvement of a 'naked' weakly solvated bicarbonate anion species in the catalytic cycle.

Scheme 6.9: Coupling reaction of butylene oxide with $\mathrm{CO}_{2}$ catalyzed by different PAPs. For details see Table 5.3 in Chapter 5.

### 6.2 Outlook

The potential applications of PAPs in the field of transition metal- and organocatalysis could be further investigated in a variety of ways. The ligand 13 might be modified to monoPAP 45 which should improve its stability and ease of synthesis (Scheme 6.10). This could be achieved by the lithiation of a biaryl bromide 43 with $n$-BuLi and subsequent reaction with $t-\mathrm{BuPCl}_{2}$. ${ }^{[258]}$ Through reaction with a lithiated phosphazene 45 could be generated. The resulting compounds could be tuned via variation of the organic substituents $\mathrm{R}^{1}-\mathrm{R}^{4}$.

Scheme 6.10: Suggested synthesis for monoPAP analogues of Buchwald's biaryl ligands.

In the field of transition metal catalysis, an interesting reaction to explore would be the Kumada cross coupling reaction of magnesium organyls with aryl chlorides. Preliminary results (Scheme 6.11) suggest reactivity of both mono- and trisPAPs for this type of reaction. Notably, it is possible to utilize nickel instead of palladium for this transformation. The compatibility of a $\mathbf{7 a}$ or $\mathbf{7 b} / \mathrm{Ni}(\mathrm{COD})_{2}$ system has also proven successful for both SuzukiMiyaura couplings as well as Buchwald-Hartwig aminations in initial screenings.

Scheme 6.11: Palladium (top) and nickel catalyzed (bottom) Kumada cross coupling with PAP bases. Preliminary results; Conditions are not optimized.

The applicability of PAP ligands in the gold catalyzed hydroamination of alkynes should be explored more in depth by a systematic investigation of the reaction conditions, substrate scope and ligands. The organocatalytic applications of trisPAPs $\mathbf{7 a}$ and $\mathbf{7 b}$, which possess the ability to deprotonate MeCN, should be explored more thoroughly. During initial studies the reaction of benzaldehyde with MeCN in the presence of $2.5 \mathrm{~mol} \%$ of $\mathbf{7 b}$ yielded the alkylnitrile condensation product in $69 \%$ yield (Scheme 6.12). This interesting reaction should be explored further with a variety of aldehydes and ketones as well as other substrates such as EtCN and $\mathrm{MeNO}_{2}$, possibly in the presence of molecular sieves for the trapping of water which is liberated during the reaction.

Scheme 6.12: Condensation of 4-methyl-benzaldehyde with MeCN catalyzed by 7b.

Additionally, the ability of $\mathbf{7 b}$ to rapidly polymerize epoxides, as shown earlier, should be investigated further, as this may prove to be an important application for the synthesis of polymers in the future.

### 6.3 Conclusion

The field of uncharged phosphorus superbases was expanded to include several new mono- and bisphosphazenyl phosphines. These novel bases have been systematically analyzed according to their basicity, nucleophilicity, chemical stability, donor capabilities and coordination behavior. They complement the missing link between extremely basic trisphosphazenyl phosphines
and traditional tertiary phosphines by combining the stability and steric properties of tertiary phosphines like $\mathrm{P} t \mathrm{Bu}_{3}$ with the extreme donor capabilities of phosphazenyl phosphines. The aforementioned parameters that were established during this work allow the easy classification of newly synthesized bases. Several applications of these bases were presented, as ligands in transition metal catalysis as well as organocatalysts in a variety of transformations.

## 7 Zusammenfassung und Ausblick

### 7.1 Zusammenfassung

Trisphosphazenylphosphane (TrisPAP) sind die stärksten derzeit bekannten metallfreien Basen der Chemie. ${ }^{[85]}$ Sie wurden in der eigenen Arbeitsgruppe von S. Ullrich erstmals eingeführt. ${ }^{[86]}$ Es stellte sich die Frage über deren Verwendung als Liganden in der Übergangsmet-all- und Organokatalyse. Ebenfalls sollte untersucht werden welchen Einfluss eine Derivatisierung dieser Verbindungen durch Austausch von ein bzw. zwei der Phosphazenylgruppen durch Alkylgruppen hat (Abbildung 7.1). Diese neu synthetisierten Verbindungen wurden systematisch analysiert bezüglich ihrer Donor-Akzeptor Eigenschaften, ihrer Basizität, ihrer chemischen Stabilität und ihrem Reaktionsverhalten.

Abbildung 7.1: Übersicht über in dieser Arbeit synthetisierten und untersuchten Phosphazenylphosphanverbindungen.

### 7.1.1 Synthese und Charakterisierung von PAP

Die Klasse der superbasischen Phosphazenylphosphane (PAP) wurde um mehrere neue Monound Bisphosphazenylphosphane erweitert. Sie wurden ausgehend von einem tertiären P(III)amid oder einem tertiären Phosphan durch Staudinger Reaktion mit TMS azid synthetisiert (Schema 7.1). Durch Reaktion dieser $N$-Silyl $\mathrm{P}(\mathrm{V})$-imide mit $\mathrm{PCl}_{3}$ und anschließender Eliminierung von Trimethylsilylchlorid wurden die Monophosphazenylphosphordichlorid Verbindungen 4a-4d erhalten. An dieser Stelle ist es möglich weitere funktionelle Gruppen durch Substitution einzuführen, allerdings stellte sich die Substitution mit $t$-Butyl Gruppen als die selektivste in einer Reihe von Alkylsubstituenten heraus. MonoPAP 5a-5f wurden auf diese Art synthetisiert.

Schema 7.1: Synthese von monoPAP 5a bis $5 \mathbf{f}$.

Als Kontrast zu den überwiegend extrem starken $\sigma$-Donoren 5a-5f wurde das Phosphoramidite 9 als ein potentiell besserer $\pi$-Akzeptor Ligand synthetisiert. Durch Reaktion von 2-6-Diisopropylphenol (dippOH) mit $\mathrm{PCl}_{3}$ und anschließender Reaktion mit 2a-Li konnte $\mathbf{9}$ erhalten werden (Schema 7.2).

Schema 7.2: Synthese von monoPAP $\mathbf{9}$ aus $\mathbf{8}$ und $\mathrm{PCl}_{3}$.

Ausserdem wurden die ersten Amino substituierten BisPAP 6a-6b durch Reaktion der korrespondierenden Phosphazene 2a-2b mit $n$-BuLi und anschließender Umsetzung mit $t$ - $\mathrm{BuPCl}_{2}$ synthetisiert (Schema 7.3).

Schema 7.3: Synthese von bisPAP 6a und 6b.

BisPAP 13 wurde mit einem, den berühmten Buchwald-Liganden nachempfundenen, Biaryl-

Rückgrat konzipiert. 11 wurde durch die Reaktion des Bromobiaryls 10 mit $n$ - BuLi und $\mathrm{P}\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{Cl}$ synthetisiert (Schema (7.4). 12 wurde erhalten durch Spaltung der P-N Bindungen mit HCl. Anschließend wurde das erhaltene Chlorophosphan mit 2a-Li umgesetzt um BisPAP 13 zu erhalten.

Schema 7.4: Synthese von 13 durch Reaktion von 2 a-Li mit 12.

Um die Nukleophilie dieser neuen PAP Liganden zu untersuchen, wurden diese mit einem Überschuss an trockenem Ethyliodid umgesetzt. Zwei mögliche mechanistische Pfade können verfolgt werden: PAP reagiert entweder als ein Nukleophil und es wird durch eine $S_{N} 2$ Reaktion ein P-ethyliertes Phosphonium PAP gebildet oder es reagiert als Base in einer $E_{2}$ Reaktion und wird dabei protoniert (Schema 7.5).

Schema 7.5: Evaluierung der Nukleophilie von PAP-Basen.

Durch quantitative ${ }^{31} \mathrm{P}-$ NMR-Messungen war es möglich, das Verhältnis von PAP-Et zu PAP$\mathrm{H}^{+}$durch Integration der entsprechenden $\mathrm{P}(\mathrm{III})$ - oder $\mathrm{P}(\mathrm{V})$-Signale zu bestimmen und somit die Nukleophilie dieser PAP zu evaluieren. Die elektronischen Eigenschaften der Liganden wurden durch den Tolman-Elektronik-Parameter (TEP) sowie die ${ }^{1} J_{(P, S e)}$-Kopplungskonstante der entsprechenden Phosphazenylphosphan Selenide bestimmt. Der TEP von MonoPAP liegt im Bereich von $2040 \pm 2$, was niedriger (elektronenreicher) ist als bekannte NHC's wie IMes $(2050.5)^{[158]}$ und $\operatorname{ImNMe}_{2}(2054.1)^{[158]}$ oder Phosphane wie $\mathrm{P} t \mathrm{Bu}_{3}(2056.1)$. ${ }^{[90]}$ Der TEP ist ähnlich wie bei Ylidenaminophosphanen (IAP) 81[159] (Abbildung [7.2) von DiElMANN und Ylid-funktionalisierten Phosphanen (YPhos) ${ }^{[59][7] \mid 73]}$ von Gessner. Die Strukturparameter dieser $\left[\mathrm{PAP}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$-Komplexe wurden durch XRD-Analysen untersucht.

Abbildung 7.2: Tolman Elektronischer Parameter (TEP) verschiedener Liganden und PAP als Nickeltricarbonylkomplex. Die genauen Werte sind Tabelle 3.3 zu entnehmen.

Die Basizität der unterschiedlichen PAP wurde durch Konkurrenzversuche von einer Vergleichsbase mit bekanntem $\mathrm{p} K_{B H^{+}}$Wert bestimmt. Zusätzlich wurde die Gasphasenbasizität (GB), die Protonenaffinität (PA) und die Basizität in Lösung (MeCN) mittels DFT berechnet. MonoPAP 5a-5f besitzen ähnliche p $K_{B H^{+}}$-Werte (MeCN) von $25 \pm 1$. Wie erwartet sind $\mathbf{6 a}$ und 6b stärker als ihre MonoPAP-Analoga 5a und 5b und schwächer als ihre TrisPAP-Analoga $\mathbf{7 a}$ und $\mathbf{7 b}$. Dies wird auch durch die berechneten $\mathrm{p} K_{B H^{+}}$-Werte bestätigt, die mit den experimentellen Werten übereinstimmen. Dieser Trend lässt sich auch für die GB und die PA dieser Verbindungen feststellen. Um die sterischen Abschirmungseffekte von PAP zu bestimmen, wurden die Kegelwinkel sowie das "buried volume" berechnet. Die Molekülgeometrien für diese Berechnungen konnten mittels DFT-Methoden erhalten werden. Mono- und BisPAP besitzen sehr hohe Kegelwinkel von etwa $200^{\circ}$, was $\mathrm{P} t \mathrm{Bu}_{3}\left(182^{\circ}\right)^{89]}$ übertrifft und im gleichen Bereich wie Gessners YPhos (199 ) liegt. ${ }^{[60]}$ Das "buried volume" folgt einem ähnlichen Trend und liegt zwischen $44-55 \%$. Um die Donor Eigenschaften dieser PAP genauer zu untersuchen wurde eine Reihe von quantenchemischen Berechnungen durchgeführt um die Stärke der $\sigma$ Donation und $\pi$-Akzeptanz durch die Änderung der Mulliken-Ladungen zu bestimmen. In diese Studie wurden PAP als starke $\sigma$-Donoren Liganden etabliert. Der $\pi$-Akzeptorcharakter wird durch Einführung von Alkylgruppen am zentralen Phosphoratom erhöht, ist aber immer noch sehr gering. Jeder Phosphazenylsubstitutent, der eine tert-Butyl Gruppe ersetzt, erhöht den $\sigma$-Donor und verringert den $\pi$-Akzeptor Charakter.

### 7.1.2 PAP als Liganden in der Übergangsmetallkatalyse

Der Einsatz von PAP als Liganden in der Übergangsmetallkatalyse wurde durch Reaktion mit einer Vielzahl an Palladiumpräkursoren erstmals untersucht. Die resultierenden Palladiumkomplexe wurden per XRD-Methoden analysiert und mit ähnlichen Strukuren verglichen (Abbildung 7.3).

Abbildung 7.3: Molekülstruktur von $\left[\mathrm{Pd}(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2^{-}}\left(\eta^{3}-\operatorname{cinn}\right) \mathrm{Cl}\right]$ (links, 35a) und $\left[\mathrm{Pd}\left((\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}\right)_{2}\right]$ (rechts, 37). Ellipsoide werden mit einer Wahrscheinlichkeit von $50 \%$ angenommen. Die Wasserstoffatome wurden aus Gründen der Übersichtlichkeit weggelassen.

Um die Möglichkeit der Anwendung dieser Liganden in Kreuzkupplungsreaktionen zu testen, wurden sie in einer Palladium-katalysierten SuZUKi-MiYAURA-Kupplungsreaktion mit einer Vielzahl von Arylboronsäuren und Arylchloriden eingesetzt (Schema 7.6). Nach Optimierung der Reaktionsbedingungen und einer Untersuchung des kinetischen Reaktionsprofils wurde eine umfangreiche Bibliothek von Aryl-Aryl'-Kupplungsprodukten erstellt. Es war möglich, elektronenreiche und neutrale Arylboronsäuren mit elektronenarmen, elektronenreichen und sterisch anspruchsvollen Arylchloriden mit Katalysatorbeladungen von $4 \mathrm{~mol} \% \mathrm{zu}$ koppeln. Das System wurde ebenfalls erfolgreich für die Kupplung von heterocyclischen Arylchloriden eingesetzt und zeigte Toleranz gegenüber einer Vielzahl von funktionellen Gruppen.

Schema 7.6: Palladium katalysierte Suzuki-MiYaura Kupplungsreaktionen. Reaktionsbedingungen: 1.0 Äq. $\mathrm{ArCl}, 1.5$ Äq. $\mathrm{ArB}(\mathrm{OH})_{2}, 2.0$ Äq. $\mathrm{NaOMe}, 4 \mathrm{~mol} \% \mathbf{5 a}$, $2 \mathrm{~mol} \%[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}$. Für eine Übersicht siehe Abbildung 4.9 in Kapitel 4.

Ein ähnlicher Ansatz wurde für die Untersuchung palladiumkatalysierter Buchwald-HartWIGAminierungen mit PAP 5c und 5d verfolgt (Schema 7.7). Es war möglich, Aniline mit elektronenreichen und neutralen Substituenten mit niedrigen Katalysatorbeladungen von $0.5 \mathrm{~mol} \%$ an Arylbromide zu koppeln. Der Einsatz von elektronenarmen Arylbromiden beinträchtigte die Ausbeute allerdings sehr stark. Sterisch anspruchsvolle Aniline wie Mesitylanilin
konnten mit 1-Bromo-4-methylbenzol in hohen Ausbeuten von bis zu $91 \%$ gekoppelt werden. Die C-N-Kupplung von sekundären elektronenreichen Aminen wie Morpholin lieferte nahezu quantitative Ausbeuten.

Schema 7.7: Palladiumkatalysierte Buchwald-Hartwig Aminierung. Reaktionsbedingungen: 1.0 Äq. ArBr, 1.5 Äq. amine, 2.0 Äq. $\mathrm{KO} t \mathrm{Bu}, 0.5 \mathrm{~mol} \% \mathbf{5 c}$ oder 5 d , $0.25 \mathrm{~mol} \%[\mathrm{Pd}(\pi-\operatorname{cinn}) \mathrm{Cl}]_{2}$. Für eine Übersicht siehe Abbildung 4.11 in Kapitel 4.

### 7.1.3 Organokatalytische Anwendungsgebiete für PAP-Superbasen

Die Superbasen katalysierte $N$-Alkylierung von Indolen wurde durch die Reaktion von Indol mit $E$-But-2-en-nitril mit verschiedenen PAP Katalysatoren untersucht. Nach einer anfänglichen Studie der Reaktionsbedingungen und einer Untersuchung des kinetischen Reaktionsprofils wurden passende Reaktionsbedingungen ermittelt (Schema 7.8). Mit Katalysatorbeladungen von $2.5 \mathrm{~mol} \%$ konnte $\mathbf{7 b}$ die $N$-Alkylierung von elektronenreichen und elektronenarmen Indolen mit einer Vielzahl von Michael-Akzeptoren wie Acrylamid und Methylacrylat mit guten bis sehr guten Ausbeuten effizient katalysieren.

Schema 7.8: PAP-katalysierte $N$-Alkylierung von Indolen. Reaktionsbedingungen: 1.0 Äq. Alken, 1.5 Äq. Indol, THF, RT, 16h. Für eine Übersicht siehe Abbildung 5.2 in Kapitel 5.

Zusätzlich konnten, durch Reaktion von PAP mit $\mathrm{CO}_{2}$, die ensprechenden PAP- $\mathrm{CO}_{2}$-Addukte erhalten werden. Diese wurden hinsichtlich ihrer Reaktivitäten, Stabilitäten und Strukturparameter untersucht. Es war möglich, eine Korrelation zwischen der Basizität des PAP und der ${ }^{1} J_{(P, C)}$-Kopplungskonstante des Addukts herzustellen. Diese Ergebnisse veranlassten eine Untersuchung über die katalytischen Anwendungsmöglichkeiten solcher PAP-CO ${ }_{2}$-Addukte für die Carboxylierung von Epoxiden (Schema 7.9). Durch Umsetzung verschiedener P-Basen (PAP) und C-Basen (Carbodiphosphorane, CDP) in Zusammenarbeit mit Morten Dittmar und Igor Martin konnten optimierte Reaktionsbedingungen bestimmt werden. Untersuchungen zu den mechanistischen Aspekten ergaben eine hohe Wahrscheinlichkeit für die Beteiligung "nackter", schwach solvatisierter Bicarbonat-Anionen am katalytischen Zyklus.

Schema 7.9: Reaktion von Butylenoxid mit $\mathrm{CO}_{2}$ mit PAP Katalysator. Für Details siehe Tabelle 5.3 in Kapitel 5.

### 7.2 Ausblick

Diese erstmaligen Einblicke in das Anwendungspotential von PAP in der Übergangsmetallsowie der Organokatalyse könnten in diversen Richtungen weiterentwickelt werden. Der Ligand 13 könnte zu MonoPAP 45 modifiziert werden, was seine Stabilität verbessern könnte und einen einfacheren Zugang zum gewünschten Biaryl-Rückgrat des Liganden gewährleisten sollte (Schema (7.10). Dies könnte durch die Lithiierung eines Biarylbromids $43 \mathrm{mit} n-\mathrm{BuLi}$ und anschließendes Umsetzen mit $t$ - $\mathrm{BuPCl}_{2}$ erreicht werden. ${ }^{[258]}$ Durch Reaktion mit einem lithiierten Phosphazen würde 45 entstehen. Die Eigenschaften der resultierenden Verbindungen könnten durch Variation der organischen Substituenten $R^{1}-R^{4}$ abgestimmt werden.

Schema 7.10: Synthesevorschlag für ein MonoPAP-Biarylliganden.

Im Bereich der Übergangsmetallkatalyse wäre eine interessante Reaktion die Kreuzkupplungsreaktion von Magnesiumorganylen mit Arylchloriden. Vorläufige Ergebnisse (Schema 7.11) deuten auf das Potential von Mono- und TrisPAP Liganden für diese Art von Reaktion hin. Insbesondere ist es möglich, Nickel anstelle von Palladium für diese Umwandlung zu verwenden. Die Kompatibilität eines $\mathbf{7 a}$ oder $\mathbf{7 b} / \mathrm{Ni}(\mathrm{COD})_{2}$-Systems hat sich auch für Suzuki-Miyaura-Kupplungen sowie für Buchwald-Hartwig-Aminierungen in ersten Untersuchungen als erfolgsversprechend erwiesen.

Schema 7.11: Palladium (oben) und Nickel-Katalysierte (unten) KumadA Kreuzkupplungsreaktionen mit PAP Liganden. Vorläufige Ergebnisse; Reaktionsbedingungen nicht optimiert.

Die Nutzung von PAP-Liganden in der goldkatalysierten Hydroaminierungsreaktionen von Alkinen sollte durch eine systematische Untersuchung der Reaktionsbedingungen, Substrate und Liganden tiefgreifender erforscht werden. Die organokatalytischen Anwendungen von trisPAP 7a und 7b zur Deprotonierung von MeCN sollte eingehender untersucht werden. In ersten Untersuchungen ergab die Reaktion von Benzaldehyd mit MeCN in Gegenwart von $2.5 \mathrm{~mol} \%$ 7b das Alkylnitril-Kondensationsprodukt in $69 \%$ Ausbeute (Schema 7.12). Diese interessante Reaktion sollte mit einer Vielzahl von Aldehyden und Ketonen sowie mit anderen Substraten wie EtCN und $\mathrm{MeNO}_{2}$, gegebenenfalls in Gegenwart von Molsieb, um das während der Reaktion abgespaltene Wasser abzufangen, weiter erforscht werden.

Schema 7.12: Durch 7b katalysierte Kondensationsreaktion von 4-Methylbenzaldehyd mit MeCN.

Darüber hinaus sollte die nachgewiesene katalytische Aktivität von 7b in der Polymerisation von Epoxiden weiter untersucht werden. Dies könnte Anwendungspotential in der Gewinnung von Polymeren finden und das Repertoir dieser Verbindungsklasse um eine weitere Anwendungsmöglichkeit ergänzen.

### 7.3 Fazit

Das Forschungsgebiet der ungeladenen Phosphorsuperbasen wurde um mehrere neue Monound Bisphosphazenylphosphane erweitert. Diese neuen Basen wurden systematisch auf ihre Basizität, Nukleophilie, chemische Stabilität, Donor-Fähigkeiten und ihr Koordinationsverhalten hin untersucht. Sie ergänzen das fehlende Bindeglied zwischen den extrem basischen Trisphosphazenylphosphanen und den traditionellen Trialkylphosphanen, indem sie die Stabilität und die sterischen Eigenschaften von tertiären Phosphanen wie $\mathrm{P} t \mathrm{Bu}_{3}$ mit den extremen Donor-Fähigkeiten der Phosphazenylphosphane kombinieren. Die oben genannten Parameter, die im Rahmen dieser Arbeit ermittelt wurden, ermöglichen eine einfache Klassifizierung der neu synthetisierten Basen. Es wurden mehrere Anwendungen dieser Basen vorgestellt, sowohl als Liganden in der Übergangsmetallkatalyse als auch als Organokatalysatoren in einer Vielzahl von Anwendungen.

## 8 Experimental Section

### 8.1 General Procedures

All reactions were carried out under inert argon atmosphere using standard SCHLENK techniques. Air or moisture sensitive substances were stored in a nitrogen flushed glovebox. Solvents were purified according to common literature procedures and stored under an inert atmosphere over molecular sieves $(3 \AA$ or $4 \AA)$. ${ }^{[259]}$ For chromatographic purifications Kieselgel 60 (less than 0.063 nm , CAS No. 7631-86-9) from MERCK was utilized. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P},{ }^{19} \mathrm{~F}$ and ${ }^{77}$ Se NMR spectra were recorded on a Bruker Avance III HD 250, Avance II 300, Avance III HD 300 or Avance III HD 500 spectrometer. Chemical shift $\delta$ is denoted relatively to $\mathrm{SiMe}_{4}\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right), 85 \% \mathrm{H}_{3} \mathrm{PO}_{4}\left({ }^{31} \mathrm{P}\right), \mathrm{SeMe}_{2}\left({ }^{77} \mathrm{Se}\right)$ or $\mathrm{CFCl}_{3}\left({ }^{19} \mathrm{~F}\right) .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were referenced to the solvent signals. Multiplicity is abbreviated as follows: $s$ (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), sept (septet), br. (broad signal). High resolution mass spectrometry was performed on a Thermo Fisher Scientific LTQ-FT Ultra or a Jeol AccuTOF GCv. IR spectra were recorded in a glovebox on a Bruker Alpha ATR-FT-IR.

### 8.1.1 Precursors and chemicals

The following precursors were synthesized according to literature procedures:
$\mathrm{P}(\mathrm{dma})_{3}{ }^{[260}, \mathrm{P}(\mathrm{pyrr})_{3}{ }^{[261]}, \mathrm{P}(t \mathrm{Bu})_{3}{ }^{[262]}, \mathrm{dma}_{3} \mathrm{PNH}^{[17]}$, pyrr $_{3} \mathrm{PNH}{ }^{[17]}$, dma ${ }_{3} \mathrm{PNTMS}^{[138]}$, $\operatorname{pyrr}_{3} \mathrm{PNTMS}^{[138]}, \mathrm{cy}_{3} \mathrm{PNTMS}^{[138]}, t-\mathrm{Bu}_{3} \mathrm{PNTMS}^{[138]}, \mathrm{dma}_{3} \mathrm{PNPCl}_{2}{ }^{138]}$, $\operatorname{pyrr}_{3} \mathrm{PNPCl}_{2}{ }^{[138]}, \mathrm{cy}_{3} \mathrm{PNPCl}_{2}{ }^{[138]}, t-\mathrm{Bu}_{3} \mathrm{PNPCl}_{2}{ }^{[138]}, \mathrm{dma}_{3} \mathrm{PNPNMe}_{2}{ }^{138]}$, pyrr $_{3} \mathrm{PNPNpyrr}^{[138]}$, (dma) $\mathrm{P}_{3} \mathrm{P}^{[85]}$, (pyrr) $\mathrm{P}_{3} \mathrm{P}^{[85]}, \mathrm{P}(\mathrm{Odipp})_{2} \mathrm{Cl}^{[143]}$, 2-bromo3', 5'dimethoxy1,1 'biphenyl ${ }^{[145]}, \mathrm{Ph}_{3} \mathrm{PAuCl}^{[263]},\left[\mathrm{Cl}_{3} \mathrm{CPCl}_{3}\right] \mathrm{AlCl}_{4}{ }^{[146]},\left[\mathrm{Cl}_{3} \mathrm{CP}\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{Cl}\right] \mathrm{AlCl}_{4}{ }^{[147]}$, $\mathrm{Cl}_{3} \mathrm{CP}\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{NH}^{[148]},\left[\mathrm{Pd}(\pi-\mathrm{cinn}) \mathrm{Cl}_{2}{ }^{[191]},\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{OPhPNH}{ }^{[149]},\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{PCl}{ }^{[264]}\right.$, $t-\mathrm{BuPCl}_{2}{ }^{[265]}$.

The following precursors were purchased and utilized without further purification:
$\mathrm{Pcy}_{3}, \mathrm{KHMDS}, \mathrm{PCl}_{5}, \mathrm{TMSN}_{3}, n$-BuLi, $t$-BuLi, $t$ - $\mathrm{BuMgCl},\left[\mathrm{NiCO}_{4}\right]$, Se (grey), dipp-OH, $\mathrm{NaBF}_{4}, \mathrm{NH}_{4} \mathrm{PF}_{6}, \mathrm{NaOH}, \mathrm{NaCl}, \mathrm{LiCl},\left[\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}\right], \mathrm{NiCl}_{2}, \mathrm{PdCl}_{2},\left[\left(\mathrm{Me}_{2} \mathrm{~S}\right) \mathrm{AuCl}\right]$, phenylboronic acid, 4-methoxy boronic acid, 2,4,6-trimethylphenylboronic acid, 2,6-dimethylchlorobenzene, 4-chlorobenzonitrile, 4-chlorotoluene, 1-chloro-4-(trifluoromethyl)benzene, 1-chloro-2-methoxybenzene, 1-chloro-4-methoxybenzene, 1-(4-chlorophenyl)ethan-1-one, 1-(4-bromo-phenyl)ethan-1-one, 2-chlorothiophene, 2-chloro-6-methoxypyridine, 5-chloro-3-methylbenzo[b/thiophene, 2-bromo-4-(tert-butyl)aniline, aniline, 2,4,6-trimethylaniline, 4-methoxyaniline, 4-fluoroaniline, 4-nitroaniline, morpholine, 4-bromotoluene, 2-bromo-1,3,5-trimethylbenzene, 4-bromobenzonitril, indole, 5-methoxy- 1 H -indole, $1 H$-indole-5-carbonitrile, $E$-but- 2 -enenitrile, methyl acrylate, 1-bromo-4-methoxybenzene, acrylamide.

The following precursors were purchased and purified according to common literature procedures ${ }^{[259]}$ :

Pyrrolidine, $\mathrm{PCl}_{3}$, EtI.

### 8.2 Synthesis

### 8.2.1 Phosphazene bases and precursors

### 8.2.1.1 Synthesis of (cy) ${ }_{3} \mathrm{PNPCl}_{2}$ (4c)

The compound was prepared analogously to literature procedures. ${ }^{[138]}$ The product was obtained as a colorless solid ( $98 \%$ ).
${ }^{1} \mathbf{H}-\mathbf{N M R}\left(\mathbf{3 0 0} \mathbf{~ M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=2.00-1.84(\mathrm{~m}, 3 \mathrm{H}), 1.83-1.72(\mathrm{~m}, 6 \mathrm{H}), 1.65-1.58$ $(\mathrm{m}, 6 \mathrm{H}), 1.53-1.46(\mathrm{~m}, 3 \mathrm{H}), 1.40-1.23(\mathrm{~m}, 6 \mathrm{H}), 1.07-0.94(\mathrm{~m}, 9 \mathrm{H})$.
${ }^{13} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left(75 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \quad \delta(\mathrm{ppm})=34.5\left(\mathrm{dd},{ }^{1} J(\mathrm{P}, \mathrm{C})=58.0 \mathrm{~Hz},{ }^{3} J(\mathrm{P}, \mathrm{C})=\right.$ $6.8 \mathrm{~Hz}), 26.9\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{C})=12.5 \mathrm{~Hz}\right), 26.6\left(\mathrm{~d},{ }^{3} J(\mathrm{P}, \mathrm{C})=2.8 \mathrm{~Hz}\right), 25.9\left(\mathrm{~d},{ }^{4} J(\mathrm{P}, \mathrm{C})=1.0 \mathrm{~Hz}\right)$.
${ }^{31} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left(121 \mathrm{MHz}, \mathrm{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=159.3\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=119.0 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right), 40.5$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=119.0 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.1.2 Synthesis of $(t \mathrm{Bu})_{3} \mathrm{PNPCl}_{2}(4 \mathrm{~d})$

The compound was prepared analogously to literature procedures. ${ }^{[138]}$ The product was obtained as a colorless solid ( $96 \%$ ).
${ }^{1} \mathbf{H}-$ NMR $\left(300 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta(\mathrm{ppm})=1.46\left(\mathrm{~d},{ }^{3} J(\mathrm{P}, \mathrm{H})=14.2 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{CCH}_{3}\right)$.
${ }^{13} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left(\mathbf{7 5} \mathbf{~ M H z}, \mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=40.3\left(\mathrm{dd},{ }^{1} J(\mathrm{P}, \mathrm{C})=47.6 \mathrm{~Hz},{ }^{3} J(\overline{\mathrm{P}, \mathrm{C})}=5.9 \mathrm{~Hz}\right.$ ${ }^{\mathrm{CCH}_{3}}$ ), $29.4\left(\mathrm{~s}, \mathrm{CCH}_{3}\right)$.
${ }^{\overline{31}} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left.\overline{(121 ~ M H z}, \mathrm{C}_{\mathbf{6}} \mathrm{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=158.3\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=133.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right), 54.3$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=133.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.1.3 Synthesis of (dma) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}(5 a)$

To a solution of [tris(dimethylamino)phosphazenyl] phosphorus dichloride (4a)
$(0.77 \mathrm{~g}, 2.76 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) in \mathrm{Et}_{2} \mathrm{O}(50 \mathrm{~mL})$ was added $t-\mathrm{BuLi}(3.00 \mathrm{~mL}$ of 1.88 m solution in pentane, $5.66 \mathrm{mmol}, 2.05$ eq.) dropwise at $-78{ }^{\circ} \mathrm{C}$. After stirring for 1 h at this temperature, the mixture was allowed to reach RT overnight. The mixture was filtered over Celite ${ }^{\circledR}$, the filter cake washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$ and the solvent removed in vacuo. [tris(dimethylamino)-phosphazenyl]-bis(tert-butyl)phosphine (5a) (0.81 g, $2.51 \mathrm{mmol}, 91 \%$ ) was obtained as a colorless solid.
${ }^{1} \mathbf{H}-\mathrm{NMR}\left(300 \mathrm{MHz}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=2.52\left(\mathrm{~d},{ }^{3} J(\mathrm{P}, \mathrm{H})=9.5 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{NCH}_{3}\right), 1.37(\mathrm{~d}$, $\left.{ }^{3} J(\mathrm{P}, \mathrm{H})=10.5 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{CCH}_{3}\right)$.
${ }^{13} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR $\left(75 \mathrm{MHz}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=36.9\left(\mathrm{t},{ }^{2} J(\mathrm{P}, \mathrm{C})=2.5 \mathrm{~Hz}\right), 33.7\left(\mathrm{dd},{ }^{1} J(\mathrm{P}, \mathrm{C})=\right.$ $12.4 \mathrm{~Hz}), 27.7\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{C})=16.2 \mathrm{~Hz}\right)$.
${ }^{\mathbf{3 1}} \mathbf{P}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR $\left(\mathbf{1 2 1} \mathbf{M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=85.4\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=100.5 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right), 31.4$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=100.5 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.
LIFDI $(+)-\mathbf{H R M S}=323.24750[\mathrm{M}-\mathrm{H}]^{+}$calc., $323.23934[\mathrm{M}-\mathrm{H}]^{+}$found.

### 8.2.1.4 Synthesis of (pyrr) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$ (5b)

To a solution of [trispyrrolidinophosphazenyl] phosphorus dichloride (4b) $(2.00 \mathrm{~g}, 5.60 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) in \mathrm{Et}_{2} \mathrm{O}(75 \mathrm{~mL})$ was added $t-\mathrm{BuLi}(6.11 \mathrm{~mL}$ of 1.88 m solution in pentane, $11.48 \mathrm{mmol}, 2.05$ eq.) dropwise at $-78{ }^{\circ} \mathrm{C}$ over 10 min . After stirring for 1 h at this temperature, the mixture was allowed to reach RT overnight. All volatile components were removed in vacuo and the residue redissolved in pentane $(30 \mathrm{~mL})$. The reaction mixture was filtered over Celite ${ }^{\circledR}$ and the filter cake was washed with pentane ( $3 \times 10 \mathrm{~mL}$ ). After removal of the solvent in vacuo [tris(pyrrolidino)phosphazenyl]bis-tert-butyl phosphine (5b) (2.10 g, $5.12 \mathrm{mmol}, 91 \%$ ) was obtained as a colorless solid.
${ }^{1} \mathbf{H}-\mathbf{N M R}\left(\mathbf{3 0 0} \mathbf{M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=3.20-3.10\left(\mathrm{~m}, 12 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2}\right), 1.63-1.54(\mathrm{~m}$, $\left.12 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2}\right), 1.42\left(\mathrm{~d},{ }^{3} J(\mathrm{P}, \mathrm{H})=10.4 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{CCH}_{3}\right)$.

### 8.2.1.12 Synthesis of Biaryl- $\mathrm{PCl}_{2}$ (12)

1-(3', 5'-dimethoxy-[1, 1'-biphenyl]-2-yl)- $N, N, N^{\prime}, N^{\prime}$-tetraethylphosphinediamine (11)
( $0.73 \mathrm{~g}, 1.86 \mathrm{mmol}, 1.0$ eq.) was dissolved in $\mathrm{Et}_{2} \mathrm{O}(30 \mathrm{~mL})$ and cooled to $0{ }^{\circ} \mathrm{C}$. Afterwards $\mathrm{HCl}(4.0 \mathrm{~m}$ solution in dioxane, $1.86 \mathrm{~mL}, 7.44 \mathrm{mmol}, 4.0 \mathrm{eq}$.$) was added dropwise over 5 \mathrm{~min}$. The mixture was allowed to reach RT and stirred for 1 h . The solution was filtered and washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$ and the solvent removed in vacuo. The resulting solid was recrystallized from Toluene / $\mathrm{Et}_{2} \mathrm{O}$. Dichloro( $3^{\prime}, 5^{\prime}$ '-dimethoxy-[1, $1^{\prime}$-biphenyl]-2-yl)phosphine (12) $(0.46 \mathrm{~g}, 1.46 \mathrm{mmol}, 79 \%)$ was obtained as a colorless solid.
${ }^{\mathbf{3 1}} \mathbf{P}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR $\left(\mathbf{1 2 1} \mathbf{M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=159.5(\mathrm{~s})$.

### 8.2.1.13 Synthesis of (dma) $\mathrm{P}_{2} \mathrm{P}$-Biaryl (13)

To a solution of Dichloro( $3^{\prime}, 5^{\prime}$ '-dimethoxy-[1, $1^{\prime}$-biphenyl]-2-yl)phosphine (12) $(50.0 \mathrm{mg}, 0.16 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) in \mathrm{Et}_{2} \mathrm{O}(10 \mathrm{~mL})$ was added a solution of $\left(\mathrm{NMe}_{2}\right){ }_{3} \mathrm{PNLi}(\mathbf{2 a -}$ $\mathbf{L i})(58.4 \mathrm{mg}, 0.32 \mathrm{mmol}, 2.0 \mathrm{eq}$.$) in \mathrm{Et}_{2} \mathrm{O}(10 \mathrm{~mL})$ dropwise at $-78{ }^{\circ} \mathrm{C}$ over 5 min . The mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h before being allowed to reach RT and stir overnight. Afterwards the solvent was removed in vacuo, dissolved in pentane ( 20 mL ), filtered over Celite ${ }^{\circledR}$ and washed with pentane $(3 \times 10 \mathrm{~mL})$. The solvent was removed in vacuo to receive (dma) $\mathrm{P}_{2} \mathrm{P}$-Biaryl (13) ( $51 \mathrm{mg}, 0.09 \mathrm{mmol}, 54 \%$ ) as a viscous oil. Notably, it was not possible to isolate this compound without impurities from $\left(\mathrm{Me}_{2} \mathrm{~N}\right)_{3} \mathrm{PNH}(\mathbf{2 a})$ or traces of mono substituted BiarylP ${ }_{1} \mathrm{PCl}$. Additionally the reaction proceeded better when the lithium organyl was isolated prior to the reaction instead of generating it in situ.

### 8.2.1.14 Attempted synthesis of Pincer phosphazene 18

18

19
$\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{OPhPNH}(\mathbf{1 7})\left(40.0 \mathrm{mg}, 0.14 \mathrm{mmol}, 1-0\right.$ eq.) was dissolved in $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$ and cooled to $-78{ }^{\circ} \mathrm{C}$. $n-\mathrm{BuLi}(0.05 \mathrm{~mL}$ of 2.5 m solution in hexane, $0.14 \mathrm{mmol}, 1.0$ eq.) was added dropwise at $-78{ }^{\circ} \mathrm{C}$ and the mixture was stirred for 1 h . Afterwards $t-\mathrm{BuPCl}_{2}(11.2 \mathrm{mg}$, $0.07 \mathrm{mmol}, 0.50$ eq. $)$ in $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$ was added dropwise and the mixture was again stirred for 1 h . Afterwards the mixture was allowed to warm up to RT overnight. The mixture was filtered over Celite ${ }^{\circledR}$ and washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$ and the solvent was removed in vacuo. ${ }^{31} \mathrm{P}-\mathrm{NMR}$ shows, that only monosubstitution has taken place leading to compound 19.
${ }^{31} \mathbf{P}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR (121 MHz, $\left.\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=177.4\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=63.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})-\mathrm{Cl}\right), 23.4$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=63.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.1.15 Synthesis of 20

20

21
$\left(\mathrm{NEt}_{2}\right)_{2} \mathrm{OPhPNH}(\mathbf{1 7})(0.35 \mathrm{~g}, 1.22 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) was dissolved in \mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$ and $n-\mathrm{BuLi}$ ( 0.47 mL of 2.5 M solution in hexane, $1.22 \mathrm{mmol}, 1.0$ eq.) was added dropwise at $-78^{\circ} \mathrm{C}$. The mixture was stirred for 1 h at this temperature before $\mathrm{PCl}_{3}(83.8 \mathrm{mg}, 0.61 \mathrm{mmol}, 0.5 \mathrm{eq}$.$) was$ added dropwise. The mixture was again stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h . Afterwards the mixture was allowed to reach RT and was stirred overnight. Afterwards it was filtered over Celite ${ }^{\circledR}$ and washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$ and the solvent was removed in vacuo. ${ }^{31} \mathrm{P}-\mathrm{NMR}$ shows a mixture of 20 and 21.

[^10]
### 8.2.1.16 Attempted synthesis of pincer phosphazene 18 via 20

18

19

20 from the previous reaction was reacted with one equivalent of $t$-BuLi at $-78{ }^{\circ} \mathrm{C}$ in $\mathrm{Et}_{2} \mathrm{O}$. After stirring for 1 h at this temperature the reaction mixture was allowed to reach RT and was stirred overnight. The mixture was filtered over Celite ${ }^{\circledR}$ and the solvent was removed in vacuo. ${ }^{31} \mathrm{P}-\mathrm{NMR}$ shows full conversion to 19.
${ }^{31} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR ( $\left.121 \mathrm{MHz}, \mathrm{C}_{6} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=177.4\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=63.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})-\mathrm{Cl}\right), 23.4$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=63.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.2 Synthesis of phosphazenyl phosphine selenides

### 8.2.2.1 General procedure for the generation of phosphazenyl phosphine selenides

To a solution of phosphine ( $0.20 \mathrm{mmol}, 1.0 \mathrm{eq}$ ) in toluene ( 5 mL ) gray selenium ( 0.25 mmol , 1.20 eq.) was added and the mixture was stirred at $90{ }^{\circ} \mathrm{C}$ for 1 h . After cooling to room temperature the mixture was filtered through a syringe filter and all volatile components were removed in vacuo. Afterwards the residue was dissolved in pentane ( 10 mL ) and filtered through a syringe filter. The solvent was removed in vacuo and the selenides were obtained as colorless to yellow solids.

### 8.2.3 Synthesis of phosphazenyl phosphine nickel carbonyl complexes

### 8.2.3.1 General procedure for the generation of phosphazene nickel tricarbonyl complexes

A solution of phosphine ( $1.00 \mathrm{eq}, 0.20 \mathrm{mmol}$ ) in toluene $(5 \mathrm{~mL})$ was added dropwise to a solution of $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right]$ in toluene $(5 \mathrm{~mL})$. The mixture was stirred for 1 h . Afterwards the solvent was removed in vacuo, the residue dissolved in pentane and filtered through a syringe filter. The solvent was removed in vacuo to yield the corresponding phosphine nickeltricarbonyl complexes as orange to red solids.

### 8.2.4 Synthesis of phosphazenyl phosphine $\mathrm{CO}_{2}$ adducts

### 8.2.4.1 Attempted Synthesis of (R) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{CO}_{2}$ (39a to 39 d )

$\mathrm{R} 1=\mathrm{NMe}_{2}$, pyrr, cy, tBu
$R 2=t B u$
$\mathrm{P}_{1} \mathrm{P}$ base ( 100 mg ) was dissolved in pentane ( 10 mL ) and cooled to $-78^{\circ} \mathrm{C}$. Afterwards the argon atmosphere was removed and replaced by a $\mathrm{CO}_{2}$ atmosphere for a total of three cycles. A white precipitate could be observed after stirring in this atmosphere for 5 min . The solution was decanted and the white precipitate was dissolved in $\mathrm{Et}_{2} \mathrm{O}$ and a ${ }^{31} \mathrm{P}-\mathrm{NMR}$ was taken. The resulting $\mathrm{P}_{1} \mathrm{P}-\mathrm{CO}_{2}$ adducts turned out to be unstable at RT and in only one case it was possible to measure this adduct. Only pure $\mathrm{P}_{1} \mathrm{P}$ base was detected in all other cases.

Data for (pyrr) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{CO} 2(39 \mathbf{b}):$
${ }^{31} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR ( $\mathbf{1 2 1} \mathbf{M H z}, \mathrm{C}_{\mathbf{6}} \mathrm{D}_{\mathbf{6}}$ ): $\delta(\mathrm{ppm})=41.9(\mathrm{~s}, \mathrm{P}(\mathrm{III})), 11.9(\mathrm{~s}, \mathrm{P}(\mathrm{V}))$.

### 8.2.4.2 Synthesis of (dma) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}-\mathrm{CO}_{2}$ (40a)

Synthetic route a)
(dma) $\mathrm{P}_{2} \mathrm{P}-(t \mathrm{Bu})(\mathbf{6 a})(100 \mathrm{mg}, 0.23 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) was dissolved in \mathrm{Et}_{2} \mathrm{O}(15 \mathrm{~mL})$, cooled to $-78{ }^{\circ} \mathrm{C}$ and freshly ground dry ice (excess) was dropped slowly into this solution. Afterwards the solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h and the solvent was removed in vacuo. (dma) $\mathrm{P}_{2} \mathrm{P}$ $t \mathrm{Bu}-\mathrm{CO}_{2}$ (40a) (109 mg, 0.23 mmol , quant.) was obtained as a white solid. This route does generate a small amount of protonated (dma) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{BuH}^{+}$as a result of the dry ice being slightly wet.

Synthetic route b)
$(\mathrm{dma}) \mathrm{P}_{2} \mathrm{P}-(t \mathrm{Bu})(\mathbf{6 a})(100 \mathrm{mg}, 0.23 \mathrm{mmol}, 1.0$ eq. $)$ was dissolved in $\mathrm{Et}_{2} \mathrm{O}(15 \mathrm{~mL})$ and cooled to $-78{ }^{\circ} \mathrm{C}$. The argon atmosphere was removed and replaced with a $\mathrm{CO}_{2}$ atmosphere for a total of three cycles. Afterwards the solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h and the solvent was removed in vacuo. (dma) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}-\mathrm{CO}_{2}$ (40a) (quant.) was obtained as a white solid.
${ }^{1} \mathbf{H}-\mathrm{NMR}\left(\mathbf{3 0 0} \mathbf{~ M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=2.50\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{H})=10.1 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{NCH}_{3}\right), 1.63(\mathrm{~d}$, $\left.{ }^{2} J(\mathrm{P}, \mathrm{H})=15.2 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{CCH}_{3}\right)$.
${ }^{13} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR $\left(75 \mathbf{M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=167.8\left(\mathrm{~d},{ }^{1} J(\mathrm{P}, \mathrm{C})=128.6 \mathrm{~Hz}, \underline{\mathrm{CO}_{2}}\right), 37.2(\mathrm{~d}$, $\left.{ }^{2} J(\mathrm{P}, \mathrm{C})=3.7 \mathrm{~Hz}, \mathrm{NCH}_{3}\right), 25.5\left(\mathrm{~s}, \mathrm{CCH}_{3}\right)$.
${ }^{31} \mathbf{P}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$-NMR $\left(\overline{\mathbf{1 2 1}} \mathbf{~ M H z}, \mathbf{C}_{\mathbf{6}} \overline{\mathbf{D}_{\mathbf{6}}}\right): \delta(\mathrm{ppm})=19.2\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=19.4 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right), 4.3(\mathrm{t}$, $\left.{ }^{2} J(\mathrm{P}, \mathrm{P})=19.4 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right)$.
MS-data is unavailable due to decomposition of the compound under MS conditions.
IR (neat) $=3002.4(\mathrm{w}), 2883.0(\mathrm{~m}), 2800.6(\mathrm{w}), 1633.0\left(\mathrm{~s}, \mathrm{CO}_{2}\right), 1478.5(\mathrm{~m}), 1455.9(\mathrm{~m})$, $1371.5(\mathrm{~m}), 1282.9(\mathrm{~s}), 1254.1(\mathrm{~s}), 1177.9(\mathrm{~s}), 1064.6(\mathrm{~m}), 969.9(\mathrm{vs}), 801.1(\mathrm{~m}), 729.0(\mathrm{~s})$, $628.1(\mathrm{~m}), 586.9(\mathrm{~s}), 514.8(\mathrm{~m}), 465.4(\mathrm{~s})$.

### 8.2.4.3 Synthesis of (pyrr) $\mathrm{P}_{2} \mathrm{P}-\mathrm{tBu}-\mathrm{CO}_{2}$ (40b)

Synthetic route a)
(pyrr) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}(\mathbf{6 b})\left(100 \mathrm{mg}, 0.17 \mathrm{mmol}, 1.0\right.$ eq.) was dissolved in $\mathrm{Et}_{2} \mathrm{O}(15 \mathrm{~mL})$, cooled to $-78{ }^{\circ} \mathrm{C}$ and freshly ground dry ice (excess) was dropped slowly into this solution. Afterwards the solution was stirred at $-78^{\circ} \mathrm{C}$ for 1 h and the solvent was removed in vacuo. (pyrr) $\mathrm{P}_{2} \mathrm{P}$ $t \mathrm{Bu}^{-\mathrm{CO}_{2}}$ (40b) (quant.) was obtained as a white solid. This route does generate a small amount of protonated (pyrr) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}-\mathrm{H}^{+}$as a result of the dry ice being slightly wet.

Synthetic route b)
(pyrr) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}(6 \mathbf{b})\left(100 \mathrm{mg}, 0.17 \mathrm{mmol}, 1.0\right.$ eq.) was dissolved in $\mathrm{Et}_{2} \mathrm{O}(15 \mathrm{~mL})$ and cooled to $-78{ }^{\circ} \mathrm{C}$. The argon atmosphere was removed and replaced with a $\mathrm{CO}_{2}$ atmosphere for a total of three cycles. Afterwards the solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h and the solvent was removed in vacuo. (pyrr) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}-\mathrm{CO}_{2}$ ( 40 b ) ( $107 \mathrm{mg}, 0.17 \mathrm{mmol}$, quant.) was obtained as a white solid.

### 8.2.5.5 Synthesis of $\left[(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{AuCl}\right]$ (32a)

Synthetic route a)
(dma) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}(5 \mathrm{a})(200 \mathrm{mg}, 0.62 \mathrm{mmol}, 1.0$ eq.) was dissolved in $\mathrm{THF}(10 \mathrm{~mL})$ and $\mathrm{PPh}_{3} \mathrm{AuCl}(307 \mathrm{mg}, 0.62 \mathrm{mmol}, 1.0$ eq.) was added. The mixture was stirred overnight under exclusion of light for 1 h . Afterward, the solvent was removed in vacuo, pentane ( 10 mL ) added and filtered hot. The solvent was removed in vacuo to yield $\left[(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{AuCl}\right]$ (32a) as a colorless solid. Impurities of $\mathrm{PPh}_{3}$ are present in this route.
Synthetic route b)
$(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}(5 \mathbf{a})(100 \mathrm{mg}, 0.31 \mathrm{mmol}, 1.0$ eq. $)$ was dissolved in toluene $(10 \mathrm{~mL})$ and $\mathrm{SMe}_{2} \mathrm{AuCl}(91.4 \mathrm{mg}, 0.31 \mathrm{mmol}, 1.0$ eq.) was added. The mixture was stirred overnight under exclusion of light. Afterward, the solvent was removed in vacuo, pentane ( 10 mL ) added and filtered hot. The solution was cooled to $-30^{\circ} \mathrm{C}$ and the resulting crystals were filtered off to yield $\left[(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{AuCl}\right](32 \mathbf{a})$ as a colorless solid.
${ }^{1} \mathbf{H}-\mathrm{NMR}\left(\mathbf{3 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right): \delta(\mathrm{ppm})=2.78\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{H})=9.9 \mathrm{~Hz}, \mathbf{1 8 H}, \mathrm{NCH}_{3}\right), 1.28(\mathrm{~d}$, $\left.{ }^{2} J(\mathrm{P}, \mathrm{H})=15.5 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{CCH}_{3}\right)$.
${ }^{13} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left(75 \mathrm{MHz}, \mathbf{C D C l}_{3}\right): \delta(\mathrm{ppm})=38.5\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{C})=3.4 \mathrm{~Hz}\right), 28.4\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{C})=\right.$ 6.7 Hz ).
${ }^{31} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR ( $121 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta(\mathrm{ppm})=86.1\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=21.6 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right), 27.3$ $\left(\mathrm{d},{ }^{2} J(\mathrm{P}, \mathrm{P})=21.3 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.5.6 Synthesis of $\left[(t B u) P_{1} P-(t B u)_{2}-A u C l\right] ~(32 d)$

$(t \mathrm{Bu}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}(5 \mathrm{~d})(110 \mathrm{mg}, 0.30 \mathrm{mmol}, 1.0$ eq. $)$ was dissolved in THF ( 10 mL ) and $\mathrm{SMe}_{2} \mathrm{AuCl}$ ( $89.6 \mathrm{mg}, 0.30 \mathrm{mmol}, 1.0$ eq.) was added. The mixture was stirred overnight under exclusion of light. Afterward, the solvent was removed in vacuo, pentane ( 10 mL ) added and filtered hot. The solution was cooled to $-30^{\circ} \mathrm{C}$ and the resulting crystals were filtered off to yield $\left[(t \mathrm{Bu}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}-\mathrm{AuCl}\right](\mathbf{3 2 d})$ as a colorless solid. Significant amounts of side products were formed in this synthesis, only trace amount of product could be detected.
${ }^{\mathbf{3 1}} \mathbf{P}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}-\mathrm{NMR}\left(\mathbf{1 2 1} \mathbf{M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=104.1(\mathrm{~s}, \mathrm{P}(\mathrm{III})), 47.6\left(\mathrm{~d},{ }^{2} J(\mathrm{P}, \mathrm{P})=8.2 \mathrm{~Hz}\right.$, $\mathrm{P}(\mathrm{V})$ ).

### 8.2.5.7 Synthesis of $\left[(\mathrm{dma}) \mathrm{P}_{2} \mathrm{P}-\mathrm{tBu}-\mathrm{AuCl}\right]$ (33a)

$(\mathrm{dma}) \mathrm{P}_{2} \mathrm{P}-(t \mathrm{Bu})(\mathbf{6 a})(107 \mathrm{mg}, 0.24 \mathrm{mmol}, 1.0 \mathrm{eq}$.$) was dissolved in toluene ( 10 \mathrm{~mL}$ ) and $\mathrm{PPh}_{3} \mathrm{AuCl}(120 \mathrm{mg}, 0.24 \mathrm{mmol}, 1.0$ eq.) was added. The mixture was stirred overnight under exclusion of light. Afterward, the solvent was removed in vacuo, pentane ( 10 mL ) added and filtered hot and transferred to a $-30{ }^{\circ} \mathrm{C}$ freezer to crystallize. The resulting crystals were filtered off and dried in vacuo to yield $\left[(\mathrm{dma}) \mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}-\mathrm{AuCl}\right](\mathbf{3 3 a})$ as a colorless solid. Impurities of $\mathrm{PPh}_{3}$ and other side products are present in this route.
${ }^{1} \mathbf{H}-\mathrm{NMR}\left(\mathbf{3 0 0} \mathbf{~ M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=2.60\left(\mathrm{~d},{ }^{3} J(\mathrm{P} ; \mathrm{H})=9.9 \mathrm{~Hz}, 27 \mathrm{H}, \mathrm{NCH}_{3}\right), 1.56(\mathrm{~d}$, $\left.{ }^{3} J(\mathrm{P}, \mathrm{H})=14.9 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{CCH}_{3}\right)$.
${ }^{13} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\}$-NMR $\left(75 \mathrm{MHz}, \mathrm{C}_{6} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=37.2(\mathrm{~d}, J(\mathrm{P}, \mathrm{C})=3.8 \mathrm{~Hz}), 37.1(\mathrm{dd}, J(\mathrm{P}, \mathrm{C})=$ $4.0 \mathrm{~Hz}, J(\mathrm{P}, \mathrm{C})=33.3 \mathrm{~Hz}), 26.7(\mathrm{~s})$.
${ }^{31} \mathbf{P}\left\{{ }^{1} \mathbf{H}\right\}$-NMR (121 MHz, $\left.\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}\right): \delta(\mathrm{ppm})=54.8\left(\mathrm{t},{ }^{2} J(\mathrm{P}, \mathrm{P})=34.2 \mathrm{~Hz}, \mathrm{P}(\mathrm{III})\right), 19.6(\mathrm{~d}$, $\left.{ }^{2} J(\mathrm{P}, \mathrm{P})=34.1 \mathrm{~Hz}, \mathrm{P}(\mathrm{V})\right)$.

### 8.2.6 Cross coupling products

### 8.2.6.1 General procedure for the Suzuki Miyaura cross couplings with phosphazenyl phosphine ligands

## Screening Procedure:

Phenylboronic acid ( $1.5 \mathrm{mmol}, 1.5 \mathrm{eq}$ ), base ( $2.0 \mathrm{mmol}, 2.0 \mathrm{eq}$ ), 1-chloro-4-methylbenzene ( $1.0 \mathrm{mmol}, 1.0$ eq.) and internal standard $1,3,5$-trimethoxybenzene ( $10 \mathrm{~mol} \%$ ) were dissolved in toluene ( 16 mL ). Ligand ( $4 \mathrm{~mol} \%$ ) and palladium cinnamylchloride dimer ( 0.5 to $2 \mathrm{~mol} \%$ ) were dissolved in toluene $(4 \mathrm{~mL})$ and stirred for 15 min at RT. The catalyst mixture was then added to the reaction mixture and the resulting suspension was stirred at $80{ }^{\circ} \mathrm{C}$ for 16 h . Aliquots were taken from the reaction mixture and transferred to mass vials. Water ( 0.2 mL ) was added to quench the reaction. The organic phase was extracted with EtOAc ( 3 x 1.0 mL )
and filtered through a cotton filled pipette. The solvent was removed in vacuo and dissolved in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. The conversion was measured through comparison of the integrals of the methyl group of the product and the $-\mathrm{OCH}_{3}$ groups of the internal standard.

## Isolation Procedure:

NaOMe ( $2.00 \mathrm{mmol}, 108 \mathrm{mg}, 2.0$ eq.) was added to a SCHLENk flask in a glovebox. In a separate flask $5 \mathrm{a}(12.9 \mathrm{mg}, 4 \mathrm{~mol} \%)$ and palladium cinnamyl chloride dimer ( $10.4 \mathrm{mg}, 2 \mathrm{~mol} \%$ ) was added. The flasks were taken out of the glovebox and toluene was added ( 16 mL and 4 mL ). To the base, boronic acid ( $1.50 \mathrm{mmol}, 1.50 \mathrm{eq}$ ) and aryl chloride ( $1.0 \mathrm{mmol}, 1.0 \mathrm{eq}$. ) was added and stirred until dissolved. The catalyst mixture was added to the reaction mixture and heated to $80^{\circ} \mathrm{C}$ for 16 h . Afterward, water ( 20 mL ) was added, and the mixture extracted with EtOAc (3x 50 mL ). In the case of insufficient phase separation, brine ( 20 mL ) was added. The organic phases were combined, dried over $\mathrm{MgSO}_{4}$ and the solvent was removed. The crude product was adsorbed onto silica and purified by flash chromatography (Hexane:EtOAc) to yield the final products.

### 8.2.6.2 Suzuki-Miyaura products

## 2,6-Dimethyl-1,1'-biphenyl (Entry 1)

### 8.2.6.3 General procedure for the Buchwald-Hartwig amination with phosphazenyl phosphine ligands

## Screening procedure:

Base ( $2.0 \mathrm{eq}, 2 \mathrm{mmol}$ ) was added to a Schlenk flask in a Glovebox. In a second flask, palladium precursor ( $0.25-2 \mathrm{~mol} \%$ ) and ligand ( $0.5-4 \mathrm{~mol} \%$ ) were added, and the flasks were removed from the Glovebox. Solvent ( 16 mL and 4 mL ) was added and stirred. Haloarene ( $1.0 \mathrm{eq}, 1.0 \mathrm{mmol}$ ), amine ( 1.5 eq. 1.5 mmol ) and internal standard ( $10 \mathrm{~mol} \%$ ) were added to the flask containing the base. The catalyst mixture was then added to the reaction mixture and stirred at $80^{\circ} \mathrm{C}$ for the specified time. Aliquots were taken from the reaction mixture and transferred to mass vials. Water $(0.2 \mathrm{~mL})$ was added to quench the reaction. The organic phase was extracted with EtOAc ( 3 x 1.0 mL ) and filtered through a cotton filled pipette. The solvent was removed in vacuo and dissolved in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$. The conversion was measured through comparison of the integrals of the methyl group of the product and the aromatic protons of the internal standard.

## Isolation procedure:

$\mathrm{KO} t \mathrm{Bu}$ ( $2.0 \mathrm{mmol}, 108.1 \mathrm{mg}, 2.0$ eq.) was added to a Schlenk flask in a glovebox. In a second flask, ligand ( $50 \mu \mathrm{~mol}$ ) and palladium cinnamyl chloride dimer ( $25 \mu \mathrm{~mol}, 13.0 \mathrm{mg}$ ) were added and dissolved in toluene ( 10 mL ) in order to create a stock solution ( $5 \mu \mathrm{~mol} / \mathrm{mL}$ ). The flasks were taken out of the glovebox and toluene ( 19 mL ) was added to the flask containing the base. To the base, amine ( $1.5 \mathrm{mmol}, 1.5 \mathrm{eq}$ ) and aryl bromide ( $1.0 \mathrm{mmol}, 1.0 \mathrm{eq}$.) was added and stirred until dissolved. To this mixture, $1 \mathrm{~mL}(5 \mu \mathrm{~mol})$ of catalyst stock solution was added and heated to $80^{\circ} \mathrm{C}$ for 1 h . Afterward, water ( 20 mL ) was added, and the mixture extracted with EtOAc ( 3 x 50 mL ). In the case of insufficient phase separation, brine $(20 \mathrm{~mL})$ was added. The organic phases were combined, dried over $\mathrm{MgSO}_{4}$ and the solvent was
removed. The crude product was adsorbed onto silica and purified by flash chromatography (Hexane:EtOAc) to yield the final products.

### 8.2.7 Alkylation of Indols

### 8.2.7.1 General procedure for the alkylation of indols

Generation of KHMDS free (pyrr) $\mathrm{P}_{3} \mathrm{P}(\mathbf{7 b})$ :
pyrrP ${ }_{3} \mathrm{P}-\mathrm{HBF}_{4}\left(\mathbf{7 b}-\mathrm{HBF}_{4}\right)(0.03 \mathrm{mmol}, 22.1 \mathrm{mg}, 2.5 \mathrm{~mol} \%)$ and KHMDS $(0.03 \mathrm{mmol}, 4.99 \mathrm{mg}$, $2.5 \mathrm{~mol} \%)$ were dissolved in toluene ( 5 mL ) and stirred for 2 h at RT. Afterward, the suspension was centrifuged, the motherliquor removed and the solvent removed in vacuo. The residue was dissolved in pentane ( 10 mL ), filtered over Celite ${ }^{\circledR}$ and washed ( $3 \times 10 \mathrm{~mL}$ ). The solvent was removed in vacuo to generate (pyrr) $\mathrm{P}_{3} \mathrm{P}(\mathbf{7 b})$ free of KHMDS.

Alkylation procedure:

Alkene ( $1.00 \mathrm{mmol}, 1.0$ eq.) was dissolved in THF ( 10 mL ) and indole ( $1.50 \mathrm{mmol}, 1.5 \mathrm{eq}$. ) was added. Afterward, (pyrr) $\mathrm{P}_{3} \mathrm{P}(7 \mathbf{b})(0.03 \mathrm{mmol}, 2.5 \mathrm{~mol} \%$ ) was added in THF and the mixture was stirred at a) RT or b) $60{ }^{\circ} \mathrm{C}$ for 1 to 16 h . Afterward, the solvent was removed, and the residue was purified by column chromatography on silica. Alternatively, $1,3,5$-trimethoxybenzene ( $10 \mathrm{~mol} \%$ ) was added and a crude NMR was taken. The integrals of the product and the internal standard were compared, and a yield was measured.

### 8.2.7.2 Alkylation products

### 8.3 Basicity measurements

The $p K_{B H^{+}}$values were determined as described in the literature. ${ }^{[85]}$ A mixture of phosphazene base ( $5.00 \mathrm{mg}, 1.00$ eq.), reference base ( $5.00 \mathrm{mg}, 1.00 \mathrm{eq}$.) and bistriflimidic acid $(5.00 \mathrm{mg}$, 1.00 eq.) was dissolved in $\mathrm{THF}-\mathrm{d}_{8}(0.60 \mathrm{~mL})$ transferred to an NMR tube and shaken. Quantitative ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra were recorded by inverse gated decoupling method with a relaxation delay of $40 \mathrm{~s} . ~ p K_{B H^{+}}$values of the THF scale (measured) were correlated to the MeCN scale using correlation equation 8.3 reported by Leito et al. ${ }^{[23}$ The $p K_{B H^{+}}$(THF) values of reference bases MTBD and $\mathrm{Ph}_{3} \mathrm{PCH}_{2}$ are 18.6 and 26.6 respectively. ${ }^{[23]}$

### 8.3.1 Example calculation

$(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}(8.57 \mathrm{mg}, 26.6 \mu \mathrm{~mol}), \mathrm{MTBD}(4.66 \mathrm{mg}, 30.4 \mu \mathrm{~mol})$ and triflimidic acid $(5.78 \mathrm{mg}, 26.6 \mu \mathrm{~mol})$ were dissolved in $\mathrm{THF}-\mathrm{d}_{8}(0.60 \mathrm{~mL})$ transferred to an NMR tube and shaken. The integrals of the resulting mixture of $(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$ and $(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2} \mathrm{H}^{+}$ were 0.67 and 0.33 . Therefore, we can calculate the molarity of $(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$ and MTBD as $17.74 \mu \mathrm{~mol}$ and $12.68 \mu \mathrm{~mol}$. The molarities of $(\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2} \mathrm{H}^{+}$and $\mathrm{MTBDH}^{+}$are the differences of starting molarity to calculated molarity.
We can now calculate the rate constant $K$ by equation 8.1.

$$
\begin{equation*}
K=\frac{n\left((\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}\right) * n\left(\mathrm{MTBDH}^{+}\right)}{n(M T B D) * n\left((\mathrm{dma}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2} \mathrm{H}^{+}\right)} \tag{8.1}
\end{equation*}
$$

Now we we can calculate the $p K_{B H^{+}}$by subtracting the logarithm of K with the $p K_{B H^{+}}$of the reference base ( $\mathrm{MTBD}=18.6$ in THF).

$$
\begin{equation*}
p K_{B H^{+}}=18.6-\log (K)=18.6-\log 2.80=18.15 \tag{8.2}
\end{equation*}
$$

We can calculate the basicity in MeCN by equation 8.3

$$
\begin{equation*}
p K_{a}(T H F)=(0.92 \pm 0.02) * p K_{a}(M e C N)-(5.15 \pm 0.51)=24.8 \pm 0.1 \tag{8.3}
\end{equation*}
$$

\end{gather*}
$$

### 8.4 General procedure for the determination of hydrolysis products

Phosphazene base ( 50 mg ), was dissolved in dioxane ( 2 mL ) and 3 mL of either (a) 1 M aqueous HCl , (b) 1 M aqueous NaOH or (c) $\mathrm{H}_{2} \mathrm{O}$ were added. The mixture was stirred for 16 h at $100{ }^{\circ} \mathrm{C}$. Afterward, the solvent was removed, and the residue dissolved in $\mathrm{CDCl}_{3} \cdot{ }^{31} \mathrm{P}$ NMR spectra as well as ESI-MS were measured to determine the stability of the respective phosphazenes.

### 8.4.1 Experimental data of hydrolysis reactions

### 8.5 Reaction of PAP's with lodoethane

PAP was dissolved in THF ( 5 mL ) and iodoethane (excess) was added. The mixture was stirred for 1 h before the solvent was removed in vacuo. The residue was redissolved in $\mathrm{MeCN}-\mathrm{d}_{3}$ and analyzed by NMR and MS spectrometry. A quantitative ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum was taken by inverse gated decoupling method with a relaxation delay of 40 s as described in the literature. ${ }^{[86]}$ The alkylation/protonation ratio was analyzed by integrating the central phosphorus atoms intensities of the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra.

### 8.5.1 Experimental data of ethylation reactions

### 8.5.1.1 (dma) $\mathrm{P}_{3} \mathrm{P}-E t$ and (pyrr) $\mathrm{P}_{3} \mathrm{P}-\mathrm{Et}$ (7a-Et and 7b-Et)

(dma) $\mathrm{P}_{3} \mathrm{P}$ and (pyrr) $\mathrm{P}_{3} \mathrm{P}$ data is given in the literature. 86]

### 8.6 Computational section

All gas phase calculations were performed at the PBE ${ }^{[153]}$-def2tvp ${ }^{[154]}$ or B3LYP ${ }^{[297]-300]} / 6$ $31 G^{*}{ }^{301]}$ level of theory. Solvent calculations were performed at the PBE-def2tzvp level of theory with the Conductor-like Polarizable Continuum Model (CPCM). ${ }^{[167]}$ All structures were optimized without geometrical constraints and their vibrational frequencies were computed in order to confirm the energy surface of the optimized geometries as a global minimum. All calculations have been carried out using the ORCA program package. ${ }^{[302}{ }^{[303]}$ Atom pairwise dispersion correction by Grimme et al. as well as auxiliary basis sets by Weigend et al. ${ }^{[304][305]}$ were utilized. The vibrational entropy was computed according to Grimme. ${ }^{306]}$ Rotational entropy computed according to Herzberg. [307]

### 8.6.1 Donor capabilities

For the determination of the donor capabilities, the optimized structures of phosphazene base and the corresponding $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes were calculated. After optimization, the molecules were aligned so that the Z-axis was aligned with the L-Ni bond. A single point frequency calculation was then carried out and the Mulliken Orbital charges were extracted. The values given were calculated as follows: ${ }^{[172]}$

$$
\begin{gather*}
\Delta s=s(L)-s(L-N i C O)  \tag{8.16}\\
\Delta p_{\sigma}=p_{z}(L)-p_{z}(L-N i C O)  \tag{8.17}\\
\Delta p_{\pi}=\left[p_{x}(L)+p_{y}(L)\right]-\left[p_{x}(L-N i C O)+p_{y}(L-N i C O)\right] \tag{8.18}
\end{gather*}
$$

The sum of the donation ability of the ligand can now be calculated with with equation 8.19: ${ }^{[172]}$

$$
\begin{equation*}
\sum \Delta=\Delta s+\Delta P_{\sigma}-\Delta P_{\pi} \tag{8.19}
\end{equation*}
$$

The ratio of $\sigma$ - to $\pi$-donor ability is described by equation 8.20 , [172]

$$
\begin{equation*}
\frac{\pi}{\sigma}=\frac{\Delta P_{\pi}}{\left(\Delta s+\Delta P_{\sigma}\right)} \tag{8.20}
\end{equation*}
$$

s refers to the sum of all Mulliken s-type orbital charges.
$p_{x, y, z}$ refers to the sum of all Mulliken $p_{x, y, z}$-type orbital charges.

### 8.6.2 Bond energies

To calculate the bond and the fragmentation energies, phosphazene bases and their respective $\left[\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}\right]$ complexes were calculated. The fragmentation energy was calculated using unrelaxed fragments of the complexes. The bond energy was calculated using relaxed fragments. ${ }^{[172]}$

$$
\begin{equation*}
E_{\text {frag,bond }}=E_{e l}\left(L-N i(C O)_{3}\right)-\left[E_{e l}(L)+E_{e l}\left(N i(C O)_{3}\right]\right. \tag{8.21}
\end{equation*}
$$

### 8.6.3 Proton Affinities and Gas phase basicity

Gas phase basicities were calculated as the Gibbs free energy of the reaction:

$$
L+H^{+} \rightarrow L H^{+}
$$

so that:

$$
\begin{equation*}
\Delta G=G_{(L H)}-\left[G_{(L)}+G_{\left(H^{+}\right)}\right] \tag{8.22}
\end{equation*}
$$

Proton affinities have been calculated as the enthalpy of the aforementioned reaction. [85]

$$
\begin{equation*}
P A=H_{\left(L H^{+}\right)}-\left[H_{(L)}+H_{\left(H^{+}\right)}\right] \tag{8.23}
\end{equation*}
$$

The values for the gas phase enthalpy and entropy of protons are:
$H_{\left(H^{+}\right)}=1.48 \mathrm{kcal} / \mathrm{mol}$
$S_{\left(H^{+}\right)}=26.02 \mathrm{kcal} /(\mathrm{mol} * K)$
$G_{\left(H^{+}\right)}=-6.28 \mathrm{kcal} / \mathrm{mol}$. ${ }^{166]}$

### 8.6.4 Cone Angles

Cone angles were calculated according to a mathematically rigorous method developed by Bilbrey et al. 109 [110] This method is based on solving for the most acute right circular cone that contains the entire ligand. A Mathematica package FindSolidAngle developed by the authors was used to compute the cone angles. $168[308]$ The inputs for cone angle calculations were optimized geometries of $[\mathrm{L}-\mathrm{Ni}]$ complexes.

### 8.6.5 Buried Volumes

Buried volumes were calculated according to a method developed by Cavallo et al. ${ }^{[309]}$ Bond radii were scaled by 1.17 , sphere radius of $3.5 \AA$, mesh spacing for numerical integration was 0.1 and H atoms were included in the calculations. The inputs were optimized geometries of [ $\mathrm{L}-\mathrm{AuCl}]$ complexes.

### 8.6.6 Basicity

All structures used for the determination of $p K_{A}$ values have been calculated using the PBE functional ${ }^{[153]}$ and def2tzvp ${ }^{[154]}$ basis set. The values have been estimated according to the following thermodynamic cycle, as shown by Shields et al. [153]

Abbildung 8.1: Thermodynamic cycle for estimating basicity in solution by Shields et. al.

The basicity can therefore be described by the following equation:

$$
\begin{align*}
p K_{(A)}= & p K_{\left(A H^{+}\right)}+\left[G_{\text {gas }}(B)-G_{\text {gas }}(A)-G_{\text {gas }}\left(B H^{+}\right)+G_{\text {gas }}\left(A H^{+}\right)+\right.  \tag{8.24}\\
& \left.\Delta G_{\text {sol }}(B)-\Delta G_{\text {sol }}(A)-\Delta G_{\text {sol }}\left(B H^{+}\right)+\Delta G_{\text {sol }}\left(A H^{+}\right)\right] / 2.303 R T
\end{align*}
$$

As reference trimethylphosphine $\left(\mathrm{PMe}_{3}\right)$ was selected for MeCN . It has been chosen because of its similar geometry, electronic structure and known $p K_{A}$ of 15.5. ${ }^{310]}$

### 8.7 Crystallographic appendix

XRD Data were collected with a Bruker D8 Quest area detector diffractometer equipped with $\operatorname{MoK} \alpha$ radiation, a graded multilayer mirror monochromator $(\lambda=0.71073 \AA)$ and a Photon100 CMOS detector or with a Stoe Stadivari diffractometer equipped with $\mathrm{CuK} \alpha$ radiation, a graded multilayer mirror monochromator $(\lambda=1.54178 \AA)$ and a Dectris Pilatus 300 K detector both using an oil-coated shock-cooled crystal at $100(2)$ K. Data collection, reduction, cell refinement and semi-empirical absorption correction (multi-scan) were performed within Bruker Apex3/Apex4 ${ }^{[311-314]}$ or Stoe X-Area. ${ }^{[315-318]}$ Structures were solved with dual-space methods using ShelXT ${ }^{[319]}$ and refined against F2 with ShelXL, ${ }^{[320]}$ all within the user interface of WinGX ${ }^{[321]}$ and ShelXLe. ${ }^{[322]}$ Carbon bonded hydrogen atoms were calculated in their idealized positions and refined with fixed isotropic thermal parameters. Hydrogen atoms connected to heteroatoms were located on the Fourier map and refined isotropically. All molecular structures were illustrated with Diamond $4 \sqrt{323 \mid 324]}$ using thermal ellipsoids at the $50 \%$ probability level. Peripheral protons as well as non-coordinating solvent molecules are omitted for clarity. In case of disorder, only the major component is displayed. Atom colors are assigned as shown below with reference to Jmol. ${ }^{[325]}$ All Crystal structures were solved and refined by Eugen Sharikow.

## List of Figures

1.1 Relationship between different definitions of acid-base concepts. ..... 2
1.2 Overview of different organic amine and amidine bases. ..... 5
1.3 Overview of different Schwesinger bases ( $\mathrm{p} K_{B H^{+}}$values in MeCN). ..... 7
1.4 MO scheme of a - $\mathrm{PR}_{3}$ fragment. ..... 8
1.5 Overview of different $N$-superbases ..... 9
1.6 Different superbases with a carbon as basicity center. ..... 11
1.7 Overview of different carbon superbases. ( $\mathrm{p} K_{B H^{+}}$in MeCN ) ..... 12
1.8 Examples of P-superbases ..... 13
$1.9 \quad A_{1}$ vibrational mode (left) and an example of $\sigma$-donation of a ligand. ..... 16
3.1 Overview over the target ligands for this work. ..... 28
$3.2{ }^{31}$ P-NMR ( $121 \mathrm{MHz} . \mathrm{C}_{6} \mathrm{D}_{6}$ ) spectra of the transformation from $\mathbf{1 a}$ to 5 a . ..... 30
$3.3{ }^{31} \mathrm{P}-\mathrm{NMR}\left(121 \mathrm{MHz} . \mathrm{C}_{6} \mathrm{D}_{6}\right)$ spectra of the reaction from 8 to 9 . ..... 31
$3.4{ }^{31}$ P-NMR shift of 5 a .6 a and $\mathbf{7 a}$ ..... 33
3.5 Molecular structure of 5 a .5 b .5 c and 5 d . ..... 36
3.6 Molecular structure of $\mathbf{9}$ and $\mathbf{6 b}$. ..... 37
3.7 Molecular structures of $17-\mathrm{HCl}$ and calculated structure of 18 . ..... 38
3.8 Reaction of 5a with EtI. ..... 40
3.9 Reaction of 5 a with $\mathrm{HCl} . \mathrm{NaOH}$ and $\mathrm{H}_{2} \mathrm{O}$. ..... 41
3.10 Overview of TEP for various ligands. ..... 44
3.11 Correlation of the CO bond lengths and $A_{1} \mathrm{C}-\mathrm{O}$ mode of PAP-Ni $(\mathrm{CO})_{3}$. ..... 44
3.12 XRD Structures of $\mathbf{2 5 a}$ and 25 d . ..... 45
3.14 XRD Structures of 22a. 23b and $\mathbf{3 0}$ ..... 48
$3.15{ }^{31} \mathrm{P}$-NMR ( 121 MHz . THF- $\mathrm{d}_{8}$ ) of Basicity measurement of 5 a . ..... 50
3.16 Thermodvnamic cycle bv Shields and coworkers. ..... 50
3.17 Sterical maps of $\mathbf{5 a}$. $\mathbf{5 b}$ b $\mathbf{5 b}$ and $\mathbf{5 d}$. ..... 53
3.18 Sterical maps of $\mathbf{6 a}$ and $\mathbf{6 a}$ ..... 53
3.19 Sterical maps of 9 and 13 . ..... 54
3.20 XRD of 32a and 33a ..... 55
3.21 Overview over the synthesized and characterized ligands in this chapter. ..... 57
4.1 General mechanism for a palladium catalyzed cross coupling reaction. ..... 59
4.3 XRD Structure of 35 a ..... 66
4.4 XRD Structure of 36 ..... 67
4.5 XRD Structure of 37 ..... 68
4.6 XRD Structure of 38 ..... 69
4.8 Reaction rate of SuZuki-MIYAURA coupling ..... 73
4.9 Scope of Suzuki-MiYaura coupling ..... 74
4.10 Reaction rate of Buchwald-Hartwig amination. ..... 76
4.11 Scope of Buchwald-Hartwig amination ..... 77
5.1 Kinetic profile of $N$-alkvlation of indoles. ..... 84
5.2 Scope of $N$-alkvlation of indoles. ..... 85
5.3 Different base- $\mathrm{CO}_{2}$, addicts ..... 86
5.5 XRD Structure of 40a ..... 88
5.6 XRD Structure of 41a ..... 88
5.7 XRD Structure of 41b ..... 89
6.1 Overview over various phosphazenvl phosphine compounds. ..... 93
6.2 Overview of TEP for various ligands. ..... 96
6.3 XRD Structure of $\mathbf{3 5 a}$ and $\mathbf{3 7}$ ..... 97
7.1 Übersicht über Phosphazenvlphosphanverbindungen ..... 103
7.2 Tolman-Elektronik-Parameter verschiedener Liganden. ..... 106
7.3 Molekülstruktur von 35a und $\mathbf{3 7}$ ..... 107
8.1 Thermodynamic cycle for estimating basicity in solution by ShieLDS et. al. ..... 170

## List of Tables

1.1 Overview of $\mathrm{p} K_{a}$ values of different substances in water. ..... 3
$3.1{ }^{31} \mathrm{P}$ shifts and ${ }^{2} I_{(P D)}$ coupling constants of PAP. ..... 35
$3.2{ }^{31} \mathrm{P}-\mathrm{NMR}$ chemical shifts of PAP-Et ${ }^{+}$to $\mathrm{PAP}-\mathrm{H}^{+}$and their ratio. ..... 39
3.3 TEP. ${ }^{13} \mathrm{C}-$ NMR and ${ }^{2} I_{\mathrm{CP}} \mathrm{C}$ of PAP. ..... 43
$3.4{ }^{31} \mathrm{P}$ and ${ }^{77} \mathrm{Se}$ shifts and ${ }^{1} \mathrm{I}_{\left.\mathrm{p} \mathrm{P}_{0}\right)}$ constants. ..... 46
3.5 GB. PA and $\mathrm{p} K_{B H^{+}}$values of PAP. ..... 51
3.6 Calculated cone and solid angles, as well as buried volumes of PAP. ..... 52
3.7 Donor capabilities of PAP. ..... 56
4.2 Overview over the performed screening reactions for the SM coupling. ..... 72
4.3 Screening conditions of BHA. ..... 75
5.1 Screening of catalvst loadings for $N$-alkvlation of indoles. ..... 82
5.2 Overview over the properties of PAP-CO $\mathrm{C}_{2}$ adducts. ..... 87
8.1 Data for basicitv measurement of (dma) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$. ..... 162
8.2 Data for basicitv measurement of (pvrr) $\mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$. ..... 162
8.3 Data for basicitv measurement of $(\mathrm{cv}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$. ..... 163
8.4 Data for basicitv measurement of $(t \mathrm{Bu}) \mathrm{P}_{1} \mathrm{P}-(t \mathrm{Bu})_{2}$. ..... 163
8.5 Data for basicitv measurement of (dma) $\mathrm{P}, \mathrm{P}-t \mathrm{Bu}$. ..... 163
8.6 Data for basicity measurement of (pvrr) $\mathrm{P}_{2} \mathrm{P}-t \mathrm{Bu}$. ..... 164

## List of Schemes

1.1 Definition of acids (1). bases (2) and salts (3) according to Arrienius. ..... 1
1.2 Reaction of an acid (HA) and a base (B) ..... 1
1.3 Dissociation of an acid. ..... 2
1.4 Competition reaction between two reactants with equilibrium constant K . ..... 3
1.5 Competition reaction between two bases in the gas phase. ..... 4
1.6 Different definitions for superbases. ..... 6
1.7 Svnthetic pathwav to (dma) $\mathrm{P}_{2}-t \mathrm{Bu}$. ..... 8
1.8 Svnthetic pathwav to DACN. ..... 10
1.9 Svnthetic pathway to TMGN. ..... 10
1.10 Synthetic pathwav to $i$ Pr-BIG. ..... 11
1.11 Svnthetic pathwav to pyrr 6 -CDP. MHPN and joYPhos. ..... 12
1.12 Svnthetic pathwav to a proazaphosphatrane. ..... 14
1.13 Svnthetic pathwav to a trisPAP and a Verkade base. ..... 15
1.14 Svnthesis of a mono- and trisIAP and $\mathrm{P}(\mathrm{tmg})_{2}$. ..... 15
1.15 Alkvlation of 6-nitroguinoline with ethvl isocvanoacetate. ..... 17
1.16 Nucleophilic aromatic substitution of iodoarenes and thiols. ..... 18
1.17 Base promoted addition of chloroform to benzaldehyde. ..... 18
1.18 Olefination between aldehydes and suolfonyls. ..... 18
1.19 Svnthesis of IAP and degradation of $\mathrm{SF}_{6}$. ..... 19
1.20 Nucleophilic substitutions catalvzed bv $\mathrm{P}_{\mathrm{t}}-\mathrm{tBu}$ ..... 19
1.21 Addition of carbonvls. $\mathrm{MeNO}_{2}$ and ketimines. ..... 20
1.22 Verkade base catalvzed reactions. ..... 21
1.23 Pd catalvzed cross couplings. ..... 21
1.24 Gold catalyzed hydroaminations. ..... 22
2.1 Design philosophy for novel PAP. ..... 23
2.2 Proposed reactivity of PAP. ..... 24
2.3 Proposed metal catalvzed cross coupling reactions with PAP ligands. ..... 24
2.4 Proposed organocatalytic transformations of PAP catalysts. ..... 25
3.1 Known svnthesis of mono- and bisPAP. ..... 27
3.2 Staudinger reaction between TMS azide and a tertiary phosphine. ..... 28
3.3 Performed svnthetic route towards monoPAPs 5 a to 5 f. ..... 29
3.4 Svnthesis of monoPAP 9 from 8 and $\mathrm{PCl}_{2}$. ..... 31
3.5 Used svnthetic route towards bisPAPs $6 \mathbf{a}$ and $6 \mathbf{b}$. ..... 32
3.6 Emploved svnthetic route to 13 . ..... 33
3.7 Attempted svnthesis for target ligand 18. ..... 34
3.8 Evaluation of the nucleophilicity of different PAP bv reaction with EtI. ..... 38
3.9 Overview over the svnthesized and discussed molecules for this section. ..... 42
3.10 Synthesis of 32a and 33a. ..... 54
4.1 Survev of electron rich ligands used in transition metal catalysis. ..... 60
4.2 Reaction of Pd sources with PAP. ..... 61
4.3 Svnthesis of 35a. $\mathbf{3 6}$ and $\mathbf{3 7}$. ..... 62
4.4 Svnthesis of $\mathbf{3 7}$ and possible decomposition pathwav of $\mathbf{3 5 a}$ to $\mathbf{3 8}$. ..... 63
4.5 Plausible mechanism for the generation of monoPAP-Pd ..... 64
4.6 Screening of PAP ligands in SM coupling. ..... 70
4.7 Screening of PAP ligands in BHA coupling. ..... 75
4.8 Overview over the performed hydroaminations of phenylacetylene with 7 a . ..... 79
5.1 Screening of PAP ligands for $N$-alkylation of indoles. ..... 82
5.3 Coupling of butvlene oxide with $\mathrm{CO}_{2}$ with different PAP. ..... 90
5.4 Catalytic cycle for the carboxylation of epoxides ..... 91
6.1 Svnthesis of monoPAP $\mathbf{5 a}$ to $\mathbf{5 f}$. ..... 94
6.2 Svnthesis of monoPAP 9 from 8 and $\mathrm{PCl}_{3}$ ..... 94
6.3 Svnthesis of bisPAP $\mathbf{6 a}$ and $\mathbf{6 b}$. ..... 94
6.4 Synthesis of 13 by reaction of $\mathbf{2 a - L i}$ with 12 . ..... 95
6.5 Evaluation of the nucleophilicity of different PAP bases. ..... 95
6.6 SUZUKI-MIYAURA coupling with 5a. ..... 97
6.7 BUCHWALD-HARTWIG amination with 5 c or 5 d . ..... 98
6.8 PAP catalvzed $N$-alkvlation of indoles. ..... 98
6.10 Suggested svnthesis for monoPAP analogues of Buchwald's biaryl ligands. ..... 99
6.11 KUMADA cross coupling with PAP. ..... 100
6.12 Condensation of 4-methyl-benzaldehyde with MeCN catalyzed by 7b. ..... 100
7.1 Svnthese von monoPAP 5a bis 5f. ..... 104
7.2 Svnthese von monoPAP 9 aus 8 und $\mathrm{PCl}_{3}$ ..... 104
7.3 Svnthese von bisPAP 6a und 6b. ..... 104
7.4 Svnthese von 13 durch Reaktion von 2 a-Li mit 12. ..... 105
7.5 Evaluierung der Nukleophilie von PAP-Basen ..... 105
7.6 SuZuki-MiYaura Kupplung mit 5a. ..... 107
7.7 Buchwald-Hartwig Aminierung mit 5c oder 5d. ..... 108
7.8 PAP-katalvsierte $N$-Alkvlierung von Indolen ..... 108
7.10 Svnthesevorschlag für ein MonoPAP-Biarvlliganden. ..... 109
7.11 Kumada Kreuzkupplung mit PAP Liganden. ..... 110
7.12 7b katalysierte Kondensationsreaktion von 4-Methylbenzaldehyd. ..... 110

[^0]:    ${ }^{\text {a Brackets correspond to the molar concentrations of the substances. }}$

[^1]:    ${ }^{\mathrm{b}}$ For more information about VERKADE bases consult these excellent reviews. 75 [78

[^2]:    ${ }^{\text {c }}$ For an excellent review of electronic properties of NHCs and the limitations of the TEP consult these references. 91]
    ${ }^{d}$ Recently the introduction of the metal ligand electronic parameter (MLEP) has been popularized as far infrared spectroscopy becomes more available. This parameter derives from the M-L vibrational mode. For further information, consult the following review. 99

[^3]:    ${ }^{\mathrm{e}}$ For an overview over different usages of various superbases consult the following book 113].

[^4]:    ${ }^{\text {a }}$ Unless otherwise stated, when referring to ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopy, the spectra were measured with proton decoupling.

[^5]:    ${ }^{\text {a }}$ From here on, the central phosphorus(III)-atom will be denoted P1 and phosphazenyl phosphorus atoms will be denoted P2-P4.

[^6]:    ${ }^{\text {a }}$ Measured via ATR-IR spectroscopy of neat substance.
    ${ }^{\mathrm{b}}$ Calculated using PBE/def2tzvp. ${ }^{[153 \mid 154]}$
    ${ }^{c}$ Measured in $\mathrm{C}_{6} \mathrm{D}_{6}$.
    ${ }^{\mathrm{d}}$ Due to low signal-to-noise ratio, no signal could be assigned unambiguously.
    ${ }^{e}$ Structures for these compounds can be found in Figure 3.10

[^7]:    ${ }^{\mathrm{b}}$ For computational details, refer to section 8.6

[^8]:    ${ }^{\text {a }}$ For more information on the mechanistic aspects, see references [188] and 198].
